[2] Includes shipments of basic lead sulfate in 1946, figure for which is withheld to avoid disclosure of individual company operations.
[3] Excludes value of basic lead sulfate; withheld to avoid disclosure of individual company operations.

The supply-demand situation in lead led to a National Production Authority Order, M–38, effective February 16, 1951, which set forth limitations on inventories of lead and materials containing lead, other than ores and concentrates. This order was amended on May 28 and again on July 26 to set forth certain limitations on the acceptance of rated orders to permit equitable distribution of such orders, provide for the creation of a set-aside reserve of pig lead to meet emergency situations, and establish limitations on the use of lead and lead products.

National Production Authority Order M–15, effective December 1, 1950, restricted civilian use of zinc metal and zinc-metal products in 1951 to an average quarterly rate of 80 percent of the use during the first 6 months of 1950. Rated orders and mandatory NPA orders were to be in addition to the civilian limitation. Inventories were restricted to a 45-day supply or to a "practicable minimum working inventory," whichever was less. This order was amended on June 15, 1951, to restrict use of Special High-Grade zinc, during the calendar quarter commencing July 1 and each calendar quarter thereafter, to an average quarterly rate of 70 percent of the use during the base period; consumption of all other zinc was to be the same as stated in the earlier order. Under NPA Order M–9, effective November 16, 1950, producers of zinc, zinc oxide, and other zinc products were not

Digitized by Google

required to accept rated orders for shipment in one month exceeding 10 percent of production.

Shipments of white lead (dry) and of the "in-oil" variety dropped 18 and 28 percent, respectively, from 1950 totals. Shipments of the "in-oil" variety, moreover, were the smallest by far since long before the beginning of the present century. White lead (dry) shipments, except for 1949 and 1918, were also smaller than at any time in more than 50 years. Litharge shipments decreased 13 percent in 1951 but were well above average yearly shipments during World War II. Shipments of red lead were approximately the same as in 1950 but considerably lower than in World War II years. Figure 1 shows trends in shipments of lead pigments for 1910–51.

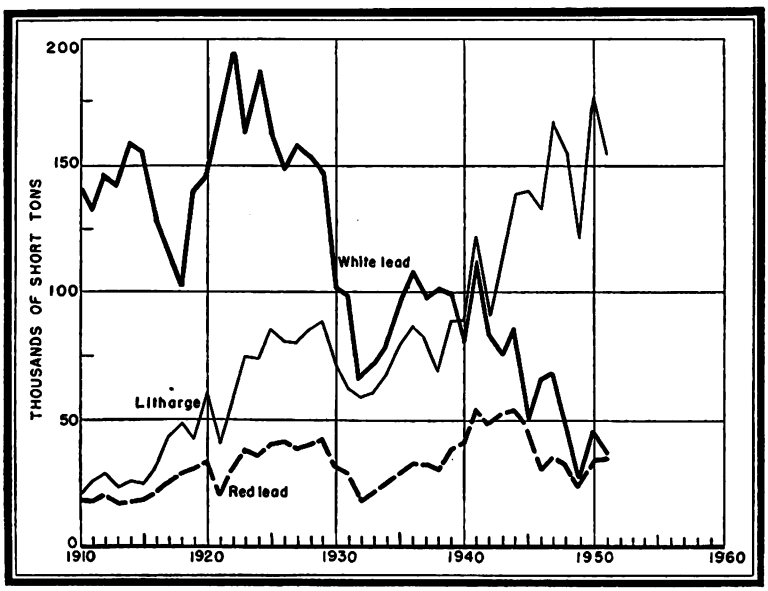

FIGURE 1.—Shipments of lead pigments, 1910–51.

Shipments of zinc oxide (lead-free), although declining 8 percent in 1951, were comparable in quantity to those during the World War II period. Shipments of leaded zinc oxide decreased 31 percent from the previous year, the largest drop among the products covered by this report. Shipments of lithopone were down 3 percent from the 1950 total and considerably lower than all years from 1925–48, inclusive. Trends in shipments of zinc pigments are shown in figure 2.

Shipments of zinc salts changed relatively little compared with 1950; zinc chloride decreased 6 percent, and zinc sulfate fell 2 percent.

The distribution of shipments of pigments to consumers in 1951 remained essentially the same as in previous years. The paint industry continued to be the largest user of white lead, leaded zinc oxide, and lithopone, accounting for approximately 81, 99, and 75 percent, respectively, of shipments. In addition, 42 percent of red-lead shipments, 22 percent of zinc oxide shipments, and 11 percent

Digitized by Google

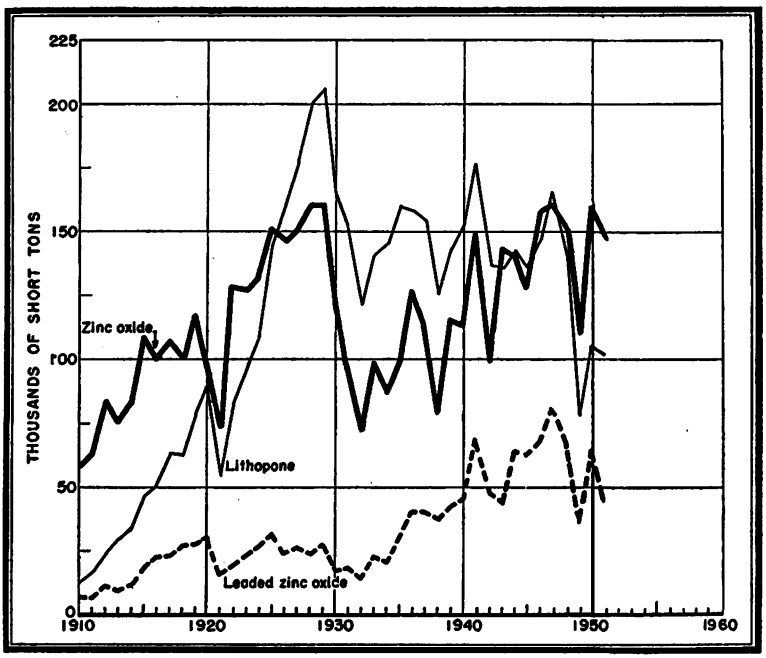

FIGURE 2.—Shipments of zinc pigments, 1910–51.

of litharge shipments went into paint manufacture. Storage-battery makers were the chief users of litharge and red lead, receiving 61 and 47 percent, respectively, of producers' shipments. Shipments of zinc oxide to the rubber industry remained on a high level, being nearly half of total shipments. Relatively small quantities of litharge, lithopone, and leaded zinc oxide are also used in manufacturing rubber. The ceramics industry ranks fourth in consumption of lead and zinc pigments, being surpassed only by the paint, storage-battery, and rubber industries. In 1951, 15 percent of litharge shipments, 7 percent of zinc oxide shipments, and smaller quantities of white lead and red lead were used in making ceramics.

Titanium pigments continued to furnish the chief competition to lead and zinc pigments in paintmaking. Production and shipments of titanium pigments were at alltime highs in 1951, 5 and 2 percent, respectively, above the previous records established in 1950. Inadequate plant capacity and shortages of raw materials have been limiting factors in titanium-pigment production for several years, preventing even greater increases. At present, the Bureau of Mines is not at liberty to publish statistics covering pigments of this class.

PRODUCTION

The value of shipments of lead and zinc pigments in 1951 (exclusive of that for basic lead sulfate, which cannot be shown) was $163,872,000, an 8-percent increase over 1950 despite a 12-percent decrease in tonnage. Lead pigments and zinc pigments comprised 54 and 46

Digitized by Google

percent, respectively, of the total value in 1951 compared with 53 and 47 percent, respectively, in 1950.

For many years, figures on "sales" were used in this series of reports as a better guide than production to activity in the pigments industry. Beginning with 1945, the base was changed to "shipments" to conform with data compiled on Bureau of Mines lead and zinc schedules. Available information for 1945 (the year of change) indicates little difference between sales and shipments in that year. In reporting tonnages of pigments, an attempt is made to avoid all duplication, one of the chief problems being that finished pigments frequently are blended to make another product. Basic lead sulfate and zinc oxide, for example, are blended to make leaded zinc oxide, and in this instance the pigment weights appear in the total for the last-named class only. Pigments consumed by producing companies to make products beyond those covered by this report—that is, paints, storage batteries, and other articles—are considered as shipments.

LEAD PIGMENTS

Shipments of lead pigments decreased 13 percent in quantity but increased 12 percent in value in 1951 compared with 1950. Substantial gains in average prices received by producers increased the total value. Shipments of white lead (dry and in oil) and litharge declined 22 and 13 percent, respectively, while red-lead shipments were slightly higher than in 1950.

Average values of lead pigments reported by producers reached alltime highs: The yearly average for white lead (dry) was $426 per ton, 27 percent above the 1950 average; red lead sold at an average of $397 per ton, an increase of 26 percent; and litharge brought $383 per ton, 31 percent higher than the 1950 average.

White Lead.—The general decline in shipments of white lead—first evident in the late 1920's—continued, as competitive pigments supplanted both classes in many paint formulas. Total shipments declined 22 percent and, except for 1949, were the lowest by far since much before the beginning of the twentieth century.

TABLE 2.—Production and shipments of lead pigments [1] in the United States, 1950–51

Pigment	1950				1951			
	Production (short tons)	Shipments			Production (short tons)	Shipments		
		Short tons	Value [2]			Short tons	Value [2]	
			Total	Average			Total	Average
White lead:								
Dry	27,954	28,506	$9,553,687	$335	22,982	23,359	$9,952,883	$426
In oil [3]	16,778	16,670	7,403,032	444	11,177	12,056	6,007,291	498
Red lead	34,066	35,072	11,013,908	314	34,065	35,352	14,025,182	397
Litharge	178,225	177,658	51,887,453	292	152,155	154,753	59,287,262	383

TABLE 3.—Lead pigments shipped by manufacturers in the United States, 1942–46 (average) and 1947–51, in short tons

Year	White lead			Basic lead sulfate or sublimed lead		Red lead	Orange mineral	Litharge
	Dry	In oil	Total	White	Blue			
1942–46 (average)[1]	[1] 38,226	34,415	[1] 72,641	[2] 5,642	[2] 1,279	47,125	169	123,081
1947	39,075	29,712	68,787	(3)	(3)	36,064	----------	167,050
1948	26,551	19,519	46,070	(3)	(3)	30,787	----------	154,775
1949	15,719	11,636	27,355	(3)	(3)	24,866	----------	121,052
1950	28,506	16,670	45,176	(3)	(3)	35,072	----------	177,558
1951	23,359	12,056	35,415	(3)	(3)	35,352	----------	154,753

[1] Basic lead sulfate for 1946 included with white lead (dry) in order to avoid disclosure of individual company operations.
[2] 1941–45 average; *see* footnote 1.
[3] Figure withheld to avoid disclosure of individual company operations.

Basic Lead Sulfate.—Because there was only one producer, the Bureau of Mines is not at liberty to publish figures on basic lead sulfate for 1946–51.

Red Lead.—Shipments of red lead in 1951 were approximately the same as in 1950 but were 25 to 35 percent lower than in World War II years.

Orange Mineral.—No shipments of orange mineral were reported in 1947–51

Litharge.—Although declining 13 percent from the 1950 total, litharge shipments remained at a comparatively high level, being exceeded only in 1947, 1948, and 1950. In recent years litharge has been the largest quantity pigment of the group covered by this report.

Battery manufacturers produced 77,000 tons of black or gray oxide or suboxide of lead in 1951 for their own use in place of litharge. This quantity compares with 80,000 tons in 1950 and 55,000 tons in 1949. Oxide production required 73,000 tons of pig lead in 1951, 77,000 tons in 1950, and 53,000 tons in 1949.

ZINC PIGMENTS AND SALTS

Owing to substantial gains in average prices received by producers, the value of shipments of zinc pigments increased 5 percent in 1951, despite an 11-percent decrease in the quantity of shipments. Shipments of zinc oxide (lead-free), the most important of the zinc pigments in tonnage and value, declined 8 percent; shipments of leaded zinc oxide fell 31 percent; and shipments of lithopone decreased 3 percent.

Producers' average values attained new peaks in 1951, surpassing the records established in 1950. Average values received by primary shippers were as follows: Zinc oxide (lead-free), $311 per ton, a gain of 21 percent; leaded zinc oxide, $320 per ton, an increase of 22 percent; and lithopone, $141 per ton, or 14 percent higher than in 1950.

Shipments of the zinc salts—zinc chloride and zinc sulfate—declined 6 and 2 percent, respectively, from 1950 totals but otherwise compared favorably with tonnages in previous years. Average values of the two compounds were $85 and $160 per ton, respectively, compared with $73 and $131 in 1950.

TABLE 4.—Production and shipments of zinc pigments and salts in the United States, 1950–51

Pigment or salt	1950				1951			
	Production (short tons)	Shipments			Production (short tons)	Shipments		
		Short tons	Value [1]			Short tons	Value [1]	
			Total	Average			Total	Average
Zinc oxide [2]	161,374	160,829	$41,439,269	$258	158,714	147,716	$45,948,219	$311
Leaded zinc oxide [2]	63,194	63,973	16,752,888	262	50,972	44,341	14,179,993	320
Lithopone	99,321	105,650	13,129,363	124	107,519	102,837	14,470,742	141
Zinc chloride, 50° B	63,843	64,564	4,703,250	73	62,527	60,730	5,152,382	85
Zinc sulfate	23,587	23,912	3,124,413	131	23,663	23,524	3,769,825	160

[1] Value at plant, exclusive of container.
[2] Zinc oxide containing 5 percent or more lead is classed as leaded zinc oxide. In this table data for leaded zinc oxide include a small quantity containing less than 5 percent lead.

TABLE 5.—Zinc pigments and salts shipped [1] by manufacturers in the United States, 1942–46 (average) and 1947–51, in short tons

Year	Zinc oxide	Leaded zinc oxide	Lithopone	Zinc chloride (50° B.)	Zinc sulfate
1942–46 (average)	133,912	57,384	139,822	55,434	18,584
1947	160,771	81,459	165,024	65,521	21,547
1948	150,958	67,441	140,033	68,701	21,513
1949	110,132	36,722	78,335	55,208	20,065
1950	160,829	63,973	105,650	64,564	23,912
1951	147,716	44,341	102,837	60,730	23,524

[1] Reported as sales before 1945.

Zinc Oxide.—Shipments of lead-free zinc oxide were 8 percent lower in 1951 than in 1950, owing partly to the reduced availability of raw materials from which the oxide is produced.

Leaded Zinc Oxide.—Shipments of leaded zinc oxide declined 31 percent in 1951, the largest decrease among the pigments covered by this report.

Four grades of leaded zinc oxide, classified according to lead content, are produced in the United States. The bulk of the output, however, is the 5- to 35-percent grade; only relatively small quantities of the other grades—5 percent or less lead, over 35 to 50 percent lead, and over 50 percent lead—are produced. Production by grades in 1951 (1950 in parentheses) was as follows: 35 percent lead and under, 46,960 (54,641) tons; over 35 percent lead, 4,012 (8,553) tons.

Lithopone.—Shipments of lithopone fell 3 percent below those in 1950 and were much lower than in all years from 1924–48, inclusive.

TABLE 6.—Production of zinc oxide (lead-free) by processes, 1946–51, as percent of total

Process	1946	1947	1948	1949	1950	1951

French process (metal and scrap)	17	17	15	17	18	18
Other	8	10	9	12	10	7
Total	100	100	100	100	100	100

Digitized by Google

The lithopone statistics in this report are given on the basis of ordinary lithopone sold as such plus the ordinary lithopone content of the high-strength product.

Consumption of ordinary lithopone in the manufacture of titanated lithopone has diminished to very small proportions. The trend has been downward almost continuously since 1937, when 19,400 tons was used in making the titanated product. The tonnage consumed for this purpose in 1951 was 55 percent below the quantity used in 1950 and the smallest on record. The lithopone figures in table 7 are included in the totals for ordinary lithopone in other tables.

TABLE 7.—Titanated lithopone produced in the United States and ordinary lithopone used in its manufacture, 1942–46 (average) and 1947–51, in short tons

Year	Titanated lithopone produced	Ordinary lithopone used	Year	Titanated lithopone produced	Ordinary lithopone used
1942–46 (average)	9,600	8,150	1949	2,000	1,700
1947	2,600	2,200	1950	3,400	2,900
1948	2,100	1,700	1951	1,550	1,300

Zinc Sulfide.—In 1951 as in several preceding years, only one company produced zinc sulfide, hence the Bureau of Mines is not at liberty to publish figures for this pigment.

Zinc Chloride.—Shipments of 50° B. solution zinc chloride declined 6 percent in 1951 but were at a comparatively high level, being exceeded in only 4 earlier years.

Zinc Sulfate.—Although zinc sulfate shipments decreased 2 percent in 1950, the total was the third-highest on record and was only 6 percent below the peak established in 1946.

RAW MATERIALS USED

Lead pigments and zinc pigments and salts are manufactured from a variety of materials, including ore, refined metal, and such secondary materials as scrap, residues, ashes, drosses, and skimmings. In 1951, as in 1950 and 1949, approximately 94 percent of the lead in pigments was derived from pig lead and the remainder from ore. Of the lead in ore used to make leaded zinc oxide, about 12 percent (14 in 1950) was from foreign sources. The sources of zinc in zinc pigments were as follows: 76 percent (73 in 1950) from ore and concentrates, 9 (9) percent from slab zinc, and 15 (17) percent from secondary materials; about 19 (22) percent of the ore used was of foreign origin.

Tables 8 and 9 give the quantities and sources of the metal used in manufacturing each pigment and salt. Pig lead is employed exclusively, either directly or indirectly, in manufacturing white lead, litharge, red lead, and orange mineral and is used also in manufacturing basic lead sulfate. The lead content of leaded zinc oxide made from basic lead sulfate, which in turn is made from pig lead, is credited to pig lead in the table. Zinc oxide is the only pigment in which considerable slab zinc is used. Ore is employed in manufacturing zinc oxide, leaded zinc oxide, lithopone, zinc sulfide, zinc sulfate, and basic lead sulfate. Over half of the zinc contained in lithopone (53 percent in 1951 and 59 in 1950) and virtually all of that in zinc chloride (100

Digitized by Google

percent in 1951 and 1950) produced in the United States are derived from secondary material. The proportion of zinc oxide production derived from metal and scrap dropped to 24 percent in 1951 compared with 29 percent in 1950. For a number of years before the United States entered World War II, there had been a large increase in the quantity of secondary zinc used in manufacturing zinc oxide. The scarcity of supplies of both metal and scrap caused the proportion of the total oxide made by the French process—which uses only metal and scrap—to drop sharply in 1942 and to continue comparatively low in 1943–46, despite the fact that the total percentage from metal and scrap rose in 1943 and continued upward almost without interruption in 1944–50. The production of zinc oxide from metal and scrap accounted for the following percentages in relation to total production: 41 percent in 1939, 16 percent in 1942, 19 percent in 1943, 22 percent in 1944, 25 percent in 1945, 26 percent in 1946, 28 percent in 1947, 26 percent in 1948, and 29 percent in 1949.

TABLE 8.—Lead content of lead and zinc pigments [1] produced by domestic manufacturers, 1950–51, by sources, in short tons

Pigment	1950				1951			
	Lead in pigments produced from—			Total lead in pigments	Lead in pigments produced from—			Total lead in pigments
	Ore		Pig lead		Ore		Pig lead	
	Domestic	Foreign			Domestic	Foreign		
White lead			35,897	35,897			27,409	27,409
Red lead			30,884	30,884			30,880	30,880
Litharge			165,428	165,428			141,215	141,215
Leaded zinc oxide	12,606	2,061		14,667	11,237	1,581		12,818
Total	12,606	2,061	232,209	246,876	11,237	1,581	199,504	212,322

[1] Excludes lead in basic lead sulfate, data for which are withheld to avoid disclosure of individual company operations.

TABLE 9.—Zinc content of zinc pigments [1] and salts produced by domestic manufacturers, 1950–51, by sources, in short tons

Pigment or salt	1950					1951				
	Zinc in pigments and salts produced from—				Total zinc in pigments and salts	Zinc in pigments and salts produced from—				Total zinc in pigments and salts
	Ore		Slab zinc	Secondary material [2]		Ore		Slab zinc	Secondary material [2]	
	Domestic	Foreign				Domestic	Foreign			
Zinc oxide	69,412	22,327	16,866	19,749	128,354	77,805	18,275	15,655	14,909	126,644
Leaded zinc oxide	26,946	5,274			32,220	21,364	4,046			25,410
Lithopone	6,380	1,507	30	11,494	19,411	7,684	2,010	59	11,098	20,851
Total pigments	102,738	29,108	16,896	31,243	179,985	106,853	24,331	15,714	26,007	172,905
Zinc chloride				14,346	14,346				14,078	14,078
Zinc sulfate	2,127	461		4,710	7,298	2,203	458		5,008	7,669

[1] Excludes zinc sulfide, data for which are withheld to avoid disclosure of individual company operations.
[2] These figures are higher than those shown in the report on Secondary Metals—Nonferrous because they include zinc recovered from byproduct sludges, residues, etc., not classified as purchased scrap material.

CONSUMPTION AND USES

LEAD PIGMENTS

White Lead.—The paint industry is by far the largest user of white lead, generally accounting for 90 percent or more of total consumption of this pigment. Available statistics show a lower percentage for 1951, but this is probably due to the inability of shippers to give complete data on end-use classification. It is known that in the past some white lead sold to the Government has been reported under "Other" for want of information on actual end use, and it is likely that a substantial part of the entire "Other" classification belongs properly under paint. Shipments to ceramics makers and manufacturers of plasticizers and stabilizers accounted for 4 and 3 percent, respectively, of total distribution in 1951.

TABLE 10.—Distribution of white lead (dry and in oil) shipments [1], 1942–46 (average) and 1947–51, by industry, in short tons

Industry	1942–46 [2] (average)	1947	1948	1949	1950	1951
Paints	66,117	61,265	40,892	24,284	38,920	28,718
Ceramics	1,282	1,665	1,369	894	1,815	1,548
Other	5,242	5,857	3,809	2,177	[3] 4,441	[3] 5,149
Total	72,641	68,787	46,070	27,355	45,176	35,415

[1] Reported as sales before 1945.
[2] Shipments of basic lead sulfate included with white lead for 1946 to avoid disclosure of individual company operations.
[3] Includes the following tonnages for plasticizers and stabilizers: 1950—1,257; 1951—1,003.

Basic Lead Sulfate.—A distribution of basic lead sulfate shipments by uses has not been available for publication since 1945, when 3,009 tons went to the paint industry, 200 tons to the rubber industry, and 686 tons to other industries. Substantial quantities of lead sulfate are also used as an intermediate product in manufacturing leaded zinc oxide. Such quantities have always been shown in this chapter under leaded zinc oxide rather than basic lead sulfate.

Red Lead.—Producers' deliveries to manufacturers of storage batteries again accounted for the largest proportion of red-lead shipments—47 percent compared with 50 percent in 1950. As in the past, the paint industry was the second largest consumer of this pigment, taking 42 percent (40 in 1950) of total shipments. Relatively small quantities were used in making ceramics.

TABLE 11.—Distribution of red-lead shipments [1], 1942–46, (average) and 1947–51, by industry, in short tons

Industry	1942–46 (average)	1947	1948	1949	1950	1951
Storage batteries	25,242	20,883	14,854	12,163	17,478	16,722
Paints	17,424	11,362	10,863	9,634	14,103	14,740
Ceramics	859	977	1,275	603	981	834
Other	3,600	2,842	3,795	2,466	2,510	3,056

[1] Reported as sales before 1945.

Digitized by Google

Orange Mineral.—No shipments of orange mineral have been reported since 1946, when 78 tons went to the ink industry, 18 tons to the color-pigment industry, and 27 tons to other industries.

Litharge.—The largest single use of litharge is for storage batteries. This use took 61 percent of total shipments in 1951 and since 1947 has accounted for roughly two-thirds of all shipments. The ceramics industry is the second largest consumer of litharge; shipments for this purpose were the second highest on record in 1951 despite an 18-percent decrease from the previous year. Shipments to insecticide makers were 47 percent less than in 1950, the largest drop among the end-use items in this report. Tonnages used for chrome pigments and varnish increased 11 and 28 percent, respectively, while shipments to oil refineries and rubber manufacturers decreased 6 and 13 percent. Shipments for use in floor coverings, regularly a very small item, increased over eight fold in 1951.

TABLE 12.—Distribution of litharge shipments [1], 1942–46 (average) and 1947–51, by industry, in short tons

Industry	1942–46 (average)	1947	1948	1949	1950	1951
Storage batteries	65,354	111,840	100,645	77,163	105,558	94,064

ZINC PIGMENTS AND SALTS

Zinc Oxide.—The distribution pattern of lead-free zinc oxide shipments was essentially the same in 1951 as in previous years. The largest tonnages went to rubber manufacturers, 48 percent (52 in 1950); the paint industry, 22 percent (25); and ceramics makers, 7 percent (8). Shipments to all consuming industries, except manufacturers of coated fabrics and textiles, whose consumption increased

TABLE 13.—Distribution of zinc oxide shipments [1], 1942–46 (average) and 1947–51, by industry, in short tons

Industry	1942–46 (average)	1947	1948	1949	1950	1951
Rubber	65,472	82,248	82,895	58,496	82,944	71,507
Paints	28,554	32,867	26,779	26,205	39,699	32,934

[1] Reported as sales before 1945.
[2] Includes the following tonnages for rayon: 1947—7,302; 1948—8,209; 1949—4,470; 1950—4,850; 1951—5,275.

Digitized by Google

15 percent, declined in 1951. One company reported shipments of oxide for chemical warfare purposes; but, since coverage for this item is not complete, the tonnage is included under the "Other" classification.

Leaded Zinc Oxide.—Leaded zinc oxide (all grades) is used almost exclusively as a pigment in paint manufacturing; in 1951 about 99 percent of total shipments was for this purpose. Small quantities (less than 1 percent of shipments) are used by the rubber industry. Shipments of leaded zinc oxide were well below production for the year, and, as a result, stocks increased considerably. The fact that leaded zinc oxide is produced from ores rather than metal or secondary materials improves its competitive position for paint manufacture when metal and scrap are in short supply.

TABLE 14.—Distribution of leaded zinc oxide shipments [1], 1942–46 (average) and 1947–51, by industry, in short tons

Total	57,384	81,459	67,441	36,722	63,973	44,341

[1] Reported as sales before 1945.

Lithopone.—Lithopone is used principally in the manufacture of paints, varnish, and lacquers; approximately three-fourths of total shipments are to these industries. In 1951 this purpose accounted for 75 percent (74 in 1950) of the total. The consumption of lithopone in paper manufacturing increased 69 percent in 1951 to become the second largest use of the pigment. In contrast, shipments for all other purposes except printing ink declined; deliveries to manufacturers of coated fabrics and textiles, rubber, and floor coverings dropped 39, 19, and 13 percent, respectively.

TABLE 15.—Distribution of lithopone shipments [1], 1942–46 (average) and 1947–51, by industry, in short tons

Industry	1942–46 (average)	1947	1948	1949	1950	1951

[1] Reported as sales before 1945.
[2] Includes a small quantity, not separable, used for printing ink, except in 1950 and 1951.
[3] Revised figure.
[4] Included in "Other" before 1950, except for those quantities reported under "Paint, varnish, and lacquers."

Zinc Chloride.—Statistics on the end-use distribution of zinc chloride shipments are not available. This salt is used principally in wood preserving, battery manufacturing, vulcanized fiber, oil refining, and as a soldering flux.

Digitized by Google

Zinc Sulfate.—The textile (rayon) industry has been the largest consumer of zinc sulfate since 1946, when agricultural use led; in 1951 the quantity used for rayon fell 10 percent from 1950 but was higher than in all years except 1950 and 1949. Agriculture and chemicals continued as the second and third largest uses, with shipments for agricultural purposes decreasing 4 percent from the previous year and shipments to producers of chemicals increasing 53 percent. Shipments for textile dyeing and printing in 1951 were almost 11 times higher than in 1950, by far the largest gain for any one end use of any of the pigments covered by this report. Shipments for flotation reagents, glue, electrogalvanizing, and paint and varnish processing decreased markedly in 1951.

PRICES

Total and average values received by producers for lead and zinc pigments and zinc salts are given in the tables in the early part of this chapter. Average values for white lead and red lead established new peaks in 1951, 17 percent and less than 1 percent, respectively, over the previous highs set in 1948. The average value for litharge was only 1 percent under the 1948 record. As previously stated, lead-pigment quotations were relatively steady throughout the year, the only notable changes occurring on October 2, when the price of lead advanced 2 cents a pound.

Average values received by producers of zinc pigments reached unprecedented highs in 1951, with gains over the previous peaks, recorded in 1950, ranging from 14 percent for lithopone to 22 percent for leaded zinc oxide. Quotations for pigments began at high levels and increased up to 2 cents a pound in October following the rise in zinc-metal prices.

New highs were also recorded for zinc chloride and zinc sulfate; average values were 16 and 22 percent, respectively, above the peaks established in 1950.

[1] Includes granulated.

FOREIGN TRADE [1]

Foreign trade in lead and zinc pigments and salts is of relatively minor importance in relation to domestic shipments of these commodities. A "favorable balance of trade"—that is, excess of value of exports over value of imports—is generally maintained with respect to these products. In 1951 the value of exports totaled $7,839,000 compared with imports valued at $2,727,000. These figures represented increases over 1950 of 155 percent for exports and 68 percent for imports.

Imports of white lead (basic carbonate) and litharge, the chief lead-compound entries, were 7 and 1 percent, respectively, of domestic shipments; and imports of zinc oxide, lithopone, and zinc chloride, the outstanding zinc-compound items, each amounted to only 1 percent of domestic shipments. Small quantities of zinc sulfate, red lead, lead suboxide, lead arsenate, and other lead compounds were also imported for consumption in 1951.

Lithopone and zinc oxide are the pigments exported in greatest tonnages from the United States. Exports of these pigments increased to 20,473 and 8,895 tons, respectively, in 1951 compared with 1950 exports of 9,357 and 3,094 tons. The 1951 export tonnages amount to 20 and 6 percent of the total shipments for these items.

Litharge, white lead, red lead, and lead arsenate are also exported by the United States, but exports constitute only a small portion of shipments by domestic producers.

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Lime[1]

By Oliver Bowles, F. M. Barsigian, and A. L. Marks

GENERAL SUMMARY

LIME is applied to a multitude of uses in many branches of industry, and as industrial activity continued its upward trend during 1951 the output of lime increased substantially. Lime sales in 1951 reached 8.3 million short tons, an increase of 10 percent over the record output of 1950. Of the total sales, 77 percent was in the form of quicklime or dead-burned dolomite and 23 percent hydrated lime. The average value of quicklime per ton increased from $10.57 in 1950 to $11.42 in 1951. Hydrated-lime value increased from $12.80 in 1950 to $12.81 in 1951. The number of active plants declined from 168 to 155.

TABLE 1.—Salient statistics of open-market lime in the United States, 1925–29 (average), 1935–39 (average), and 1949–51

[1] Selling value, f. o. b. plant, excluding cost of containers.

As indicated in figure 1, the use of lime in industry has attained such importance that chemical and refractory lime sales have followed closely for many years the trend of industrial production and since 1945 have been considerably higher than the level of industrial activity. On the other hand, the use of lime in the building trades has progressively declined in relative importance compared with other major uses. Sales of building lime have failed to keep pace with the indicated level of new construction (fig. 1).

Figure 2 shows the trends in sales of lime by principal uses over a period of years.

[1] Figures in this chapter pertain chiefly to open-market lime, excluding coverage of most captive lime operations.

Digitized by Google

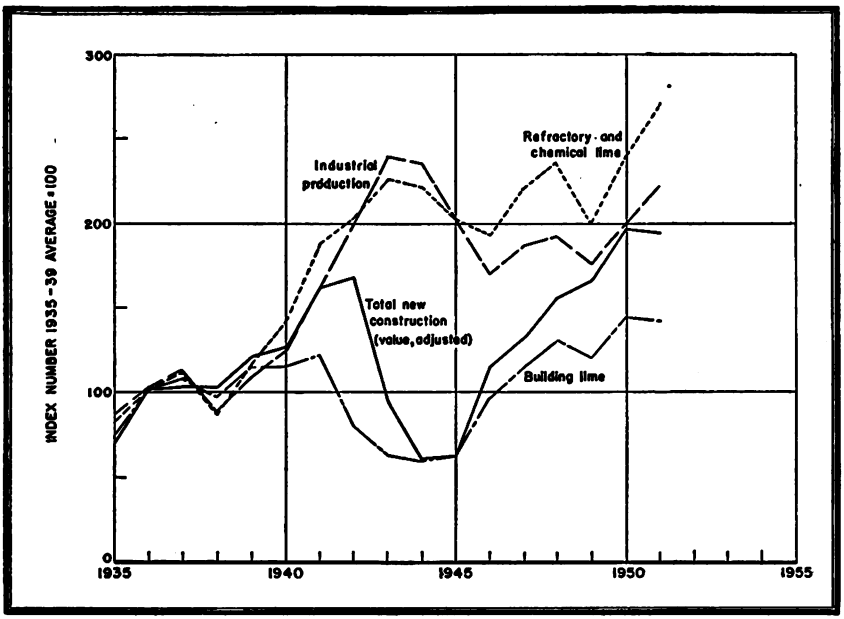

FIGURE 1.—Sales of building lime compared with total new construction and sales of refractory and chemical lime compared with industrial production, 1935–51. Units are reduced to percentages of the 1935–39 average. Statistics on value of construction (adjusted to 1939 prices) from the U. S. Department of Commerce (Statistical Abstract of the United States, 1952, p. 725) and on industrial production from the Federal Reserve Board.

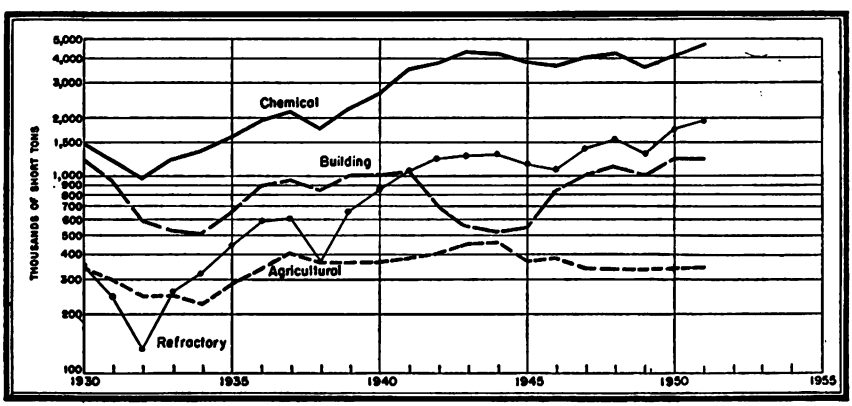

FIGURE 2.—Major uses of lime, 1930–51.

DOMESTIC PRODUCTION

Production (as indicated by sales) of open-market lime increased 10 percent in quantity and 16 percent in value from 1950 to 1951. The major gains in volume of production were in chemical and industrial lime, 14 percent, and refractory lime (dead-burned dolomite), 12 percent. Agricultural lime sales gained 3 percent, while building lime decreased 1 percent. Chemical, industrial, and refractory lime sales combined accounted for 81 percent of the total. Building lime was 15 percent of the total and agricultural 4 percent.

Digitized by Google

Captive Tonnage.—The statistics included in this chapter pertain primarily to open-market lime, but in some instances relatively small quantities of captive tonnage are included where it is particularly desirable to show complete figures for consumption by use. Specifically, in the figures for lime sales in the United States in 1951, there was included a total of 535,179 short tons of captive tonnage, used by producers, distributed as follows: 52,985 tons for building, 353,904 tons for metallurgical uses, 98,684 tons for miscellaneous chemical uses, and 29,606 tons of refractory lime (dead-burned dolomite). A more complete figure for total lime production can be obtained by adding to the total given herein the quantity calculated from the limestone tonnages (shown in the chapter on Stone in this volume) consumed in the uses in which limestone is generally calcined.

[1] Includes Hawaii and Puerto Rico.
[2] Selling value, f. o. b. plant, excluding cost of container.
[3] Includes lime used by producers (captive tonnage) as follows—1950. 450,191 tons, $3,977,905; 1951: 535,179 tons, $4,933,013.
[4] Less than ±0.5 percent.

Size of Plants.—As indicated in table 3, the consistent trend toward fewer and larger plants continued in 1951. The total number of plants reporting declined by 13; the reduction in number was confined entirely to the smaller plants. Plants producing 5,000 tons or less accounted for only 1 percent of the total. The 26 plants producing individually 100,000 tons or more contributed 60 percent of the total output in 1951, whereas the 21 plants in this size range produced 56 percent in 1950.

[1] Less than 0.5 percent.

PRODUCTION BY STATES

As in 1950, open-market lime was produced in 32 States and 2 Territories. Ohio, Pennsylvania, and Missouri continued to be the leading producers. These 3 States together contributed 56 percent of the United States total output in 1951.

Hydrated Lime.—Most of the lime sold is in the form of quicklime and the balance as hydrated lime. The proportion of hydrated to total lime in 1949 was 27 percent; in 1950, 25 percent; and in 1951, 23 percent. Production by States is indicated in table 5.

TABLE 5.—Hydrated lime sold by producers in the United States, 1950–51, by States

Virginia	r 9	73,856	836,864	9	68,875	807,538
Other States [1]	r 35	276,922	3,503,142	29	277,044	3,796,545
Total	109	1,885,101	24,121,563	105	1,919,783	24,587,110

[1] Includes the following States and number of plants in 1951 (1950 same as 1951 unless shown differently in parentheses): Arizona 3 (2), Arkansas 1, Connecticut 1, Florida 1, Indiana 1, Maine 1, Michigan 1, Minnesota 1, Montana 0 (1), Nevada 2, New Jersey 1 (3), New York 2, Oklahoma 1, Oregon 0 (2), Puerto Rico 2 (3), Utah 2, Washington 1, West Virginia 3, and Wisconsin 5 (6).

CONSUMPTION AND USES

Geographic data on sales of lime by uses are given in table 6. Although it is necessary to conceal many figures to avoid revealing confidential information, the table shows, in general, the more important uses to which the lime of each State is applied and the relative importance of each State as a lime producer.

Table 7 is of particular interest because it indicates the wide diversity in the uses of lime in industry. The chemical and other industrial uses have attained increasing importance during recent years; in 1951, 57 percent of the total output was applied to such uses compared with 55 percent in 1950. Nearly all of the major industrial uses showed substantial gains over 1950. The quantities of lime used for fluxing purposes in the steel industry gained 17 percent, for paper manufacture 19 percent, for making calcium carbide 20 percent, in glassworks 13 percent, for ore concentration 16 percent, in sewage and trade-waste treatment 10 percent, and in water purification 2 percent. The quantities of lime used in insecticides and related products and in sugar refining each declined 1 percent, while that used in tanneries declined 18 percent. Refractory lime (dead-burned dolomite) increased 12 percent.

The quantities of lime used in agriculture and in the building trades showed little change. Agricultural applications gained 3 percent, while building uses declined 1 percent.

The sales distribution of hydrated lime by uses is indicated in table 8.

[1] Included with "Undistributed" to avoid disclosure of individual operations.
[2] Bleach used in paper mills excluded from "Bleach" and included with "Paper mills."
[3] Includes citrates, tartrates, and miscellaneous food products.
[4] Includes flotation, cyanidation, bauxite purification, and magnesium manufacture.
[5] Includes barium and vanadium processing, cupola, gold recovery, and unspecified metallurgical uses.
[6] Includes alcohol, alkalies, asphalt (1951 only), medicines and drugs (1951 only), oil drilling, petrochemicals (glycol), plastics, polishing compounds, retarder, sulfur, tobacco, varnish (1951 only), and miscellaneous industrial uses.
[7] Includes lime used by producers (captive tonnage) as follows—1950: 456,191 tons, valued at $3,977,905; 1951: 535,179 tons, $4,933,013.

Grand total, hydrated lime	1,885,101	24,121,563	12.80	1,919,783	24,557,110	12.81

[1] Includes cement products, glass, glue, grease (lubricating), medicines and drugs, oil-well drilling, rubber, wood distillation, and miscellaneous industrial uses.

To furnish a more comprehensive picture of the various materials used for liming land, table 9 shows, in addition to agricultural lime, the quantities of oystershell, limestone, and calcareous marl that are applied to soil amendment.

TABLE 9.—Agricultural lime and other liming materials sold by producers in the United States, 1950–51, by kinds

Kind	1950				1951			
	Short tons		Value		Short tons		Value	
	Gross weight	Effective lime content [1]	Total	Average	Gross weight	Effective lime content [1]	Total	Average
Lime:								
Quicklime	103,823	88,250	$1,037,222	$9.99	118,673	100,870	$1,144,083	$9.64
Hydrated lime	228,864	160,200	2,567,149	11.22	224,946	157,460	2,568,525	11.42
Oystershells (crushed) [2]	55,075	25,890	[3] 321,157	5.89	75,528	35,500	411,616	5.45
Limestone	10,348,820	9,093,950	30,393,075	1.57	19,400,610	9,118,290	31,051,933	1.60
Calcareous marl	347,843	146,090	246,451	.71	269,955	113,380	233,787	.87
Total		9,514,380	[3] 34,568,054			9,525,500	35,409,944	

[1] Calculated upon basis of average percentages used by the National Lime Association, as follows: Quicklime (including lime from oystershells), 85 percent; hydrated lime, 70 percent; pulverized uncalcined limestone and oystershells, 47 percent; calcareous marl, 42 percent.
[2] Figures compiled by Fish and Wildlife Service.
[3] Revised figure.

Apparent Consumption by States.—Lime plants are widely distributed in the United States. Although most of the lime manufactured is used in local markets, some States produce a surplus while other areas are deficient in supplies. Accordingly, as indicated in table 10, considerable quantities enter interstate trade. Furthermore, limes vary considerably in physical and chemical properties, and the specialized needs of consuming industries commonly demand shipments from distant points. The principal States that exported lime beyond their borders in 1951 were Ohio, Missouri, Pennsylvania, Virginia, and West Virginia. Data on origin and destination of lime shipments, by States and groups of States, are given in tables 11 and 12.

TABLE 10.—Apparent consumption of open-market lime in continental United States in 1951, by States, in short tons

State	Sales by producers	Shipments from State [1]	Shipments into State	Apparent consumption

[1] Data cover period January through July; effective August, not separately classified.

PRICES

Prices of lime continued to advance in 1951; the average selling price, f. o. b. plant, was $11.74 per short ton compared with $11.13 in 1950. The average selling price of quicklime in 1951 was $11.42 ($10.57 in 1950) and of hydrated lime $12.81 ($12.80 in 1950).

FOREIGN TRADE [2]

Imports.—As indicated in tables 14 and 15, imports of lime into the United States are small and show little change from year to year. They originate chiefly in Canada to satisfy local needs in border areas, particularly in the State of Washington.

[2] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

NEW DEVELOPMENTS

Effective October 1951, the Bureau of Mines inaugurated a new statistical service comprising regular monthly reports summarizing lime shipments.

Calcination problems are receiving unusual attention in current literature. Kiln efficiencies have been discussed in detail by Azbe in a series of nine articles.[3] A discussion by Seaman is of special interest to operators of rotary kilns.[4] Theory and practice of limestone calcination have been discussed by Cunningham.[5]

A method has been patented for making by a quick process a lime putty having the desirable properties of putties ordinarily kept for long periods in aging tanks.[6]

High-pressure hydration, which has been applied to shaft kiln products, is now being applied to lime produced in rotary kilns.[7]

Metallic calcium is a unique coproduct manufactured by the New England Lime Co., at Canaan, Conn. The market for calcium and its alloys is expanding because of increasing chemical and metallurgical applications.

Digitized by Google

The chemical applications of lime have been discussed by Boynton [8] and also are covered in a report of the National Lime Association.[9]

Committee C–7 on Lime of the American Society for Testing Materials has been concentrating on specifications of lime for leather tanning and for silica-brick manufacture, on new methods of test for iron content and available lime, and on a new slaking test.

Magnesium

By H. B. Comstock

GENERAL SUMMARY

CONSUMPTION of primary magnesium during 1951 increased 98 percent above 1950 consumption. The rising demand was met and exceeded by the increase in production, which was 160 percent above 1950 production. Six of the seven Government-owned magnesium plants were reactivated during 1951 and produced 48 percent of the year's primary output. The remaining 52 percent came from the privately owned Dow Chemical Co. plant at Freeport, Tex., the sole producer of primary magnesium during 1946–50. At the close of 1951, stocks of primary magnesium, distributed almost equally in producers' and consumers' inventories, were slightly above 2 months' supply at the rate of consumption during December. Recovery of magnesium from secondary sources in 1951 increased 22 percent over 1950.

The price of domestic primary magnesium remained at 24.5 cents per pound throughout 1951.

The demand for primary magnesium in the defense program during 1951 was reflected strongly in increased production of structural products and purchases for the National Stockpile.

World production of primary magnesium during 1951 was estimated at 80,000 metric tons (88,000 short tons), almost twice that in 1950. About one-half was produced by the United States. The remainder was produced chiefly by the U. S. S. R., United Kingdom, Canada, France, Norway and Italy.

DOMESTIC PRODUCTION

Primary.—The production of primary magnesium in 1951 was 40,881 tons or 160 percent above production in 1950. Output from the Dow Chemical Co. plant at Freeport, Tex., was 52 percent of 1951 production. This plant had been the sole producer of primary magnesium during 1946–50. The remaining 48 percent of the output in 1951 was produced in 6 of the 7 Government-owned magnesium plants which had been idle and held in standby condition since 1945. The seventh, a silicothermic plant at Luckey, Ohio, was used for production of beryllium.

The reactivation program for the six Government-owned plants, begun in 1950, was completed by December 31, 1951. This brought the annual production capacity of primary magnesium ingot in the United States to 121,000 short tons.

TABLE 2.—Production of primary magnesium in the United States, 1947–51, by months, in short tons

Month	1947	1948	1949	1950	1951
January	1,398	883	988	1,002	1,876
February	1,232	830	884	913	1,709
March	1,472	887	988	948	1,885
April	1,153	801	958	957	2,043
May	926	797	987	972	2,194
June	848	766	950	1,175	2,512
July	905	792	985	1,332	2,998
August	849	809	970	1,400	3,418
September	886	819	974	1,635	4,166
October	912	873	941	1,690	5,147
November	870	814	969	1,760	6,010
December	893	932	1,004	1,942	6,923
Total	12,344	10,003	11,598	15,726	40,881

The value placed upon these six plants when they were shut down at the close of World War II was $74,240,000. The cost of shutting down the six plants and maintaining them until reactivation was estimated at $2,155,400. Reactivation cost was approximately $12,500,000. The cost of building the six plants in 1941–43 was $106,000,000. Time to build 6 new magnesium plants of the same types and capacities and get them into full production was estimated at 2 years, assuming that steel and electrical equipment were easily available. However, under conditions that existed in these industries during 1950 and 1951, a greater lapse of time might have been experienced before completion.

Under the reactivation program, the Government-owned plants were operated by various industrial organizations on management contracts and/or leases for production of magnesium for defense. Actual production of magnesium in the reactivated Government-owned plants was begun in March 1951 at Canaan, Conn. This silicothermic plant, with a rated annual capacity of 5,000 tons, and the 5,000-ton silicothermic plant at Wingdale, N. Y., which began production in November 1951, were operated by Nelco Metals, Inc. Under the management contract, these 2 reactivated plants were scheduled to operate for 2 years at cost plus a fixed fee.

Digitized by Google

The Velasco, Tex., plant reported initial production of 157 tons in April 1951. This electrolytic plant, with an annual capacity of 36,000 tons, was operated by Dow Chemical Co., owner of the magnesium plant at Freeport, Tex. That company contracted to produce 80,000 tons of primary magnesium at the Velasco plant, at current market price, during an estimated period of 2½ years. Under the terms of the rental contract, the Government was to pay for all repairs to the plant and assume all increases in costs resulting from changes in wage scales. This plant proved to have the lowest cost of operation in 1951 of all of the reactivated Government-owned plants.

In June 1951 the 10,000-ton silicothermic plant at Manteca, Calif., operated by Kaiser Magnesium Co., started production. The Government contract with the company covered a 5-year commitment for production at this reactivated plant, for cost plus a fixed fee. The contract was subject to cancellation at any time after the plant had been in operation 1 year and 9 months.

By the close of August 1951 the 18,000-ton electrolytic plant at Painesville, Ohio, operated by Diamond Magnesium Co., and the 24,000-ton silicothermic plant at Spokane, Wash., had begun production, bringing the total output to 1,826 tons in the Government-owned plants that month. The Diamond Magnesium Co. contract with the Government covered rehabilitation of the Painesville plant and operation of the plant for a 2-year period at cost plus a fixed fee.

The Spokane plant was operated by Pacific Northwest Alloys, Inc., a subsidiary of Chromium Mining & Smelting Corporation, a Canadian company. The Government lease agreement with Pacific Northwest Alloys covered operation of the Spokane plant for 2½ years, or until 48,000 tons of magnesium should have been produced and delivered, at cost plus a fixed fee.

In September 1951 production in the Government-owned plants rose to 2,443 tons, in October to 3,229 tons, and in November to 4,166 tons, or 48 percent of their total rated annual capacity. By December 1, 1951, these plants were producing at the rate of 60 percent of their annual capacity.

Secondary.—Total recovery of secondary magnesium, including alloying ingredients and secondary magnesium incorporated in primary ingot, was 11,526 short tons in 1951 compared with 9,476 (revised) tons in 1950. Of this quantity 9,093 tons was recovered from 10,388 tons of magnesium-base scrap in 1951. The remaining 2,433 tons was recovered from aluminum scrap. Old scrap constituted about 59 percent of the magnesium scrap consumed compared with 62 percent in 1950, which indicated a continuous rising percentage of new scrap as consumption of mangesium continued to increase. Of the 1951 recovery, 5,662 tons was in ingot form, 1,675 tons in castings, 25 tons in magnesium-alloy shapes, 3,393 tons in aluminum-base alloys, 55 tons in zinc and other alloys, 615 tons in anodes and strip for cathodic protection, and 101 tons in chemicals and other nonrecoverable forms.

More magnesium scrap was consumed in 1951 than was received. Stocks at the end of 1951 were 676 tons lower than at the beginning of the year.

Additional information on secondary magnesium may be found in the Secondary Metals—Nonferrous chapter of this volume.

Digitized by Google

CONSUMPTION AND USES

Total consumption of primary magnesium in 1951 amounted to 35,710 tons, an increase of 17,659 tons above 1950 consumption and 5,171 tons below 1951 production.

In 1951 the curves of magnesium production and consumption moved up much faster than those of any other structural metal. The demand for magnesium in the defense program during 1951 was evidenced by the increased consumption of the primary metal in structural products. Production of sand castings and die castings during 1951 was almost four times the quantity produced in 1950. The rise in requirements for large, intricate magnesium castings in both jet and reciprocating aircraft engines explained a major portion of the increase in production of sand castings. Main frames and the housings and miscellaneous parts of the air-compression system of turbojet engines were built entirely of magnesium castings. In 1951 wide use was made of magnesium in gun turrets and other attached ordnance equipment, while increasing use was made of the metal in air-portable ordnance and construction equipment.

The use of magnesium increased in a wide variety of wrought products in 1951. The greatest increase was in the production of stretch-formed sheet for airframes. A limited quantity of annealed sheet was worked cold. However, heat was required for more severe forming.

The use of magnesium in forgings increased from 104 tons in 1950, to 735 tons in 1951. They were used extensively in applications

[2] Less than 0.5 ton.
[3] Includes primary metal consumed in making secondary alloy, and as a reducing agent in production of titanium.

where pressure-tightness was important. Unlike aluminum and steel, the high-strength magnesium alloys ordinarily used for aircraft forgings are not easily hammer forgeable and are forged in presses to avoid cracking. Capacity of presses in use during 1951 ranged from 1,400 tons to 18,000 tons. In 1951, the Air Force began the installation of an additional press of 50,000-ton capacity, which was expected to be in operation by the close of 1952.

The use of approximately 500 tons of magnesium as a reducing agent in production of titanium in 1951 established a new use that would expand as production of titanium increased, if the same reduction process were continued in operation. The quantity of magnesium used in 1951 as a scavenger and deoxidizer was the highest ever to have been reported and almost trebled the amount used in 1950.

Two other large increases in 1951 were in the use of magnesium in aluminum alloys and for cathodic protection.

STOCKS

Inventories of primary magnesium on December 31, 1951, were slightly above 2 months' supply, almost equally divided between producers' and consumers' stocks. Government agencies continued to hold surplus quantities of magnesium left from stocks which were accumulated during World War II, and purchases for the national stockpile were increased during 1951.

PRICES

The base price of primary magnesium in the United States, which had increased three times during 1950, remained at 24.5 cents per pound throughout 1951, in conformity with the General Ceiling Price Regulation issued January 26, 1951.

Digitized by Google

FOREIGN TRADE [1]

Imports.—During 1951 imports of magnesium, most of which were scrap metal, increased to 3,979 tons, over 4 times the imports of 1950; they were received from 28 countries, as compared with 10 countries in 1950. About 90 percent of metal and scrap imported in 1951 came from Italy (1,000 tons), United Kingdom (547 tons), Germany (537 tons), France (479 tons), Japan (438 tons), Austria (236 tons), Canada (213 tons), and India (153 tons). Tariff rates on magnesium in 1951 remained as follows: Metallic, 20 cents per pound; alloys, powder, sheets, tubing, wire, manufactures, etc., 20 cents per pound on magnesium content plus 10 percent ad valorem; and metallic scrap, duty free.

TABLE 4.—Magnesium imported for consumption and exported from the United States, 1947–51

[U. S. Department of Commerce]

Year	Imports						Exports			
	Metallic and scrap		Alloys (magnesium content)		Sheets, tubing, ribbons, wire, and other forms, (magnesium content)		Metal in primary form		Powder, ribbons, and metal in other forms	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

[1] Less than 0.5 ton.

Exports.—Total exports of magnesium in 1951 were 761 tons, a 16-percent decrease from the 908 tons shipped in 1950. Of the metal exported in primary form during 1951, 435 tons was delivered to Mexico, 92 to Canada, and 48 to other countries.

Canada received 70 tons of the metal exported as powder, ribbons, and other forms; Saudi Arabia received 31 tons; Japan, 23 tons; Venezuela, 22 tons; and other countries, 40 tons.

TECHNOLOGY

Better working techniques were developed by the magnesium industry in 1951. Progress in developing impact-extrusion techniques resulted in the commercial production of the magnesium-cell battery in 1951. The magnesium impact-extrusion process, as practiced in 1951, consists of four operations: Slug preparation; impact extrusion; can trimming; and can cleaning. Slugs used for impact extruding could be cast, powder compact, extruded bar, or plate. They were made by parting on a lathe or screw machine, sawing from bar stock, casting, shearing from plate and bar, and from powder. Further

studies of extrusion techniques were in process in 1951 to develop the economical production of such items as collapsible tubes for toothpaste, salves, creams, etc., shell cases, shields for electronic devices, caulking guns, blow torches, flashlight cases, and drinking cups.[2]

Magnesium is the easiest of commercial metals to machine. When it is worked in the temperature range of 450° to 700° F., it is possible to accomplish, in a single draw, all that could be done in three operations in steel, brass, or aluminum. Magnesium-alloy sheet and extrusions are worked in much the same manner as other metals. Magnesium is well adapted to hot-spinning techniques. Small quantities of parts may be spun to close tolerances with inexpensive tools. By the close of 1951 magnesium spinnings were being made in thicknesses ranging from 0.032 inch to over 1.25 inches.

The Bureau of Mines continued research during 1951 to develop a more efficient thermic process of producing magnesium, utilizing dolomite as the source of the metal.

The silicothermic process, as practiced in 1951 in the Government-owned magnesium plants, is described briefly as follows: Dolomite is calcined and mixed with ferrosilicon containing 75 percent silicon, and the mixture is briquetted. The briquets are charged into tubular retorts of chrome-nickel steel. The retorts are heated and evacuated. The magnesium oxide in the calcined dolomite is reduced by the silicon, producing magnesium vapor and leaving a residual dicalcium silicate containing iron, magnesium, and other materials. The magnesium vapor distills from the charge and is condensed into crystals on a removable condenser, the end of which projects from the furnace. The process has the advantage of producing metallic magnesium in one operation directly from the calcine. One ton of magnesium requires about 14 tons of raw dolomite or 7 tons of calcined dolomite and about 1.25 tons of 75-percent-grade ferrosilicon.

The average loss of metal in melting magnesium crystals to form ingot was 11 percent in the silicothermic plants during 1951; and the remelting cost was estimated at 3 cents per pound of ingot produced.

The research work conducted by the Bureau of Mines in the 1930's upon production of magnesium by the use of ferrosilicon as a reducing agent led to the establishment, during World War II, of the large silicothermic plant at Spokane, Wash., where low-cost power and fuel were available. Magnesium-rich ores and ferrosilicon were plentiful in that area and in many other localities throughout continental United States. An ample supply of dolomite was near each of the operating silicothermic plants.

The silicothermic plants have been proved to be advantageous as standby plants because of the simplicity of design and operation. The equipment was easily and economically stored after World War II and did not deteriorate in storage to any great extent. Another advantage was the saving of electric energy. When the retorts in the silicothermic plants were heated by the use of other means than electricity, the production of 1 pound of magnesium required approximately 4½ kilowatt-hours of electricity, which was consumed in production of the reducing agent ferrosilicon. The electrolytic plants have consumed 10 kilowatt-hours of electric current for each pound

[2] Patton, T. L., Impact Extrusion of Magnesium: Iron Age, vol. 168, No. 13, September 27, 1951, pp. 81–85.

Digitized by Google

of magnesium ingot produced. This saving of electricity has been an important factor in times of defense emergency.

During 1951 the Bureau of Mines continued research toward the development of new magnesium alloys having greater strength and better resistance to corrosion.

WORLD REVIEW

World production of primary magnesium in 1951 was estimated at 80,000 metric tons, or about 100 percent above the 1950 total. World markets continued to gain, both for military and civilian consumption. The United States again led in the production and consumption of magnesium for military and civilian uses.

[1] Magnesium is also produced in Australia, Soviet zone of Germany, and U. S. S. R., but production data are not available; estimate by author of chapter included in total.
[2] Data not available; estimate by author of chapter included in total.
[3] Revised figure.
[4] British and American zones only.
[5] Includes secondary metal.
[6] Estimated figure.
[7] Includes magnesium alloys.

Canada.—All the primary magnesium produced in Canada in 1951 came from Dominion Magnesium, Ltd., at Haley, Ontario. The plant employed the Pidgeon process, using dolomite as a source of magnesium and ferrosilicon as a reducing agent. The company owned several dolomite deposits; but the largest, near Haley, was the only one operated in 1951. This deposit has been estimated to contain 4,000,000 tons of ore, adequate for approximately 70 years at the rate of depletion in 1951 and if worked by quarrying methods then used. Erection of a new plant at Beauharnois, Quebec, with annual capacity of 6,000 long tons, was begun in 1951; it was to produce 75-percent grade ferrosilicon. The plant was expected to be ready to start operating early in 1953. It was being built by Electric Reagents (Quebec), Ltd., a subsidiary of Dominion Magnesium, Ltd., and was to be operated by Chromium Mining & Smelting Corp. This plant was expected to furnish requirements of ferrosilicon for the production of magnesium that had been previously imported from Norway.[3]

Digitized by Google

The greater portion of the magnesium exported from Canada in 1951 was sent to the United Kingdom, but most of the output of ingot was fabricated in Canada for defense aircraft. Light Alloys, Ltd., a subsidiary of Dominion Magnesium, Ltd., at Renfrew, Ontario, was the largest producer of magnesium alloys in Canada.[4]

Italy.—Production of magnesium in Italy in 1951 came from the one silicothermic plant at Bolzano. This plant, with an annual capacity of approximately 3,000 metric tons, appeared to be of adequate capacity to meet domestic demands, with a small surplus for export.[5]

Japan.—Although the Ube plant of Riken Kinzoku was reported to be intact, no production of magnesium in Japan has been reported since 1945. A large supply of electric power and considerable reconstruction funds through Government aid would have been required before production of magnesium could be resumed. The Light Metal Association estimated Japan's requirements for magnesium in the 1952 fiscal year at 1,200 tons.[6]

Norway.—Production of magnesium in Norway was started in 1951 at the Herøya Elecktrokjemiske Fabriker A/S (HEFA) plant in South Norway, at the rate of 3,000 metric tons a year. High-quality dolomite and brines were being used in this plant, which was originally constructed for the use of sea water as a source of magnesium.[7]

U. S. S. R.—No figures were published on magnesium production in Russia in 1951. However, it was believed that production of the metal had greatly increased since the reported transfer to that country of the Aachen, Germany, plant in 1950. Magnesium raw materials were known to be readily available in many localities. In addition to sea water and coastal lagoon salt brines, salt lakes containing magnesium salts extended from the Crimea across the deserts of Kazakstan to the Irtysh River valley in western Siberia. An extensive bed of magnesium chloride occurred in the Solikamsk-Bereznike Basin of the northern Urals. Immense deposits of magnesite have been reported at Satka and the Khalilovo in the southern Urals and in Siberia.

United Kingdom.—In July 1951 the magnesium-extraction plant of Magnesium Elektron, Ltd., at Clifton Junction, Manchester, resumed production after about 4 years of idleness. Between 3 and 4 years of consumption of the metal from stocks created an acute shortage of both primary and secondary magnesium, which developed early in 1951. It became necessary for the Government to control usage and to assume responsibility for future supplies, whether imported from abroad or from domestic production.

The increased cost of electric power in Great Britain made the 1951 cost of power required to produce primary magnesium equal the total cost of crude metal in 1936. This made it virtually impossible to produce the metal by the electrolytic process in England in competition with countries like the United States, Canada, or Norway, where fuel and power were available at lower cost, for increased production of metals.[8]

Technological and commercial progress in Great Britain in 1951 was reported in the development and use of magnesium alloys for castings and wrought products, in jet aircraft, and in propeller turbine engines. Worldwide demand for the new alloys, containing zirconium and zinc, led to issuance of licenses for their production in the United States, Canada, Australia, Sweden, Switzerland, France, and Holland.[9]

About 75 percent of Britain's annual magnesium consumption has always been used in the form of casting alloys. Most of its magnesium foundries were working at capacity by the end of 1951.

Magnesium Compounds

By Donald R. Irving and F. P. Uswald

GENERAL SUMMARY

DOMESTIC production of crude magnesite, caustic-calcined and refractory magnesia, and dead-burned dolomite all increased during 1951 as a result of the steel-industry expansion. Additional expansion of production facilities is planned to meet further projected increases in iron- and steel-making capacity. Production of other magnesium compounds, such as high-grade magnesias and magnesium chloride, increased because of the high level of industrial and defense activity.

TABLE 1.—Salient statistics of magnesite, magnesia, and dead-burned dolomite in the United States, 1947–51

	1947	1948	1949	1950	1951
Crude magnesite:					
Mined:					
Short tons	375,993	(1)	287,315	429,392	670,167

Average per ton	$6.91	(1)	$6.79	$7.20	$6.72
Caustic-calcined magnesia:					
Sold or used by producers:					
Short tons	26,831	33,209	32,505	41,447	49,981
Value	$2,508,624	$3,380,528	$3,109,381	$4,136,898	$4,810,379
Average per ton [3]	$93.50	$101.80	$95.66	$99.81	$96.24
Refractory magnesia:					
Sold or used by producers:					
Short tons	314,921	330,069	250,389	335,440	432,197
Value	$10,127,585	$13,444,587	$10,477,856	$14,915,864	$18,400,131
Average per ton [3]	$32.16	$40.73	$41.85	$44.47	$42.57
Dead-burned dolomite:					
Sold by producers:					
Short tons	1,395,203	1,544,755	1,318,708	1,759,443	1,966,460
Value	$14,295,359	$17,847,182	$15,930,226	$21,725,560	$26,375,313
Average per ton	$10.25	$11.55	$12.08	$12.35	$13.41

[1] Figures withheld to avoid disclosure of individual company operations.
[2] Partly estimated; most of crude is processed by mining companies, and very little enters open market.
[3] Average receipts f. o. b. mine shipping point.

DOMESTIC PRODUCTION

Magnesite.—Domestic production of crude magnesite in 1951 was 670,167 short tons, an increase of 56 percent over 1950. This was the second largest annual tonnage on record, being exceeded only by the 1943 war-year production of 754,832 short tons.

Magnesia.—Refractory magnesia sold and used by producers reached an alltime high of 432,197 short tons, an increase of 29 percent over the previous high year (1950), reflecting the increased output of basic steel and the construction of new basic open-hearth furnaces. The domestic iron and steel industry consumed a record 114,837,112 long tons of iron ore during 1951 and had a rated annual capacity of 108,587,670 short tons of steel at the year end. Annual capacity exceeding 121,000,000 short tons was projected for January 1, 1954.

Digitized by Google

Since basic open-hearth furnaces represent about 87 percent of the total steel-making capacity, further expansion of refractory magnesia production was anticipated.

Production of caustic-calcined magnesia in 1951 increased to 49,981 short tons, a 21-percent gain over 1950.

TABLE 2.—Magnesia sold or used by producers in the United States, 1950–51, by kind and source

Magnesia	From magnesite, brucite, and dolomite [1]		From well brines, raw sea water, and seawater bitterns [1]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1950						
Caustic-calcined	6,418	$740,369	35,029	$3,396,529	41,447	$4,136,898
Refractory	232,283	9,358,483	103,157	5,557,371	335,440	14,915,854
Total	238,701	10,098,852	138,186	8,953,900	376,887	19,052,752
1951						
Caustic-calcined	7,689	889,624	42,292	3,920,755	49,981	4,810,379
Refractory	295,243	10,610,788	136,954	7,789,343	432,197	18,400,131
Total	302,932	11,500,412	179,246	11,710,098	482,178	23,210,510

[1] Magnesia made from a combination of dolomite and sea water is included with that from sea water.

Dolomite.—Sales of dead-burned dolomite, the bulk of which goes to the iron and steel industry, reached an alltime high of 1,966,460 short tons in 1951, an increase of 12 percent over the previous high reached in 1950.

Additional information on dolomite may be found in the Stone and Lime chapters of this volume.

TABLE 3.—Dead-burned dolomite sold in and imported into the United States, 1946–51

Year	Sales of domestic		Imports [1]		Year	Sales of domestic		Imports [1]	
	Short tons	Value	Short tons [2]	Value		Short tons	Value	Short tons [2]	Value
1946	1,077,983	$10,101,707	-------	-------	1949	1,318,708	$15,930,226	1,851	$72,680
1947	1,395,203	14,295,359	53	$2,194	1950	1,759,443	21,725,560	2,127	86,425
1948	1,544,755	17,847,182	2,427	91,613	1951	1,966,460	26,375,313	2,719	128,207

[1] "Dead-burned" basic refractory material consisting chiefly of magnesia and lime.
[2] Includes weight of immediate container.

Other Magnesium Compounds.—Sales of light and heavy high-grade magnesias in 1951 increased over 1950. Production of magnesium chloride increased sharply as demand from the magnesium-metal industry continued to increase.

Precipitated magnesium carbonate	10	60,530	8,415	1,177,999	51,987

[1] In addition to the compounds shown, magnesium chloride, hydroxide, nitrate, phosphate, and sulfate were produced. Figures for these items are withheld to avoid disclosure of individual company operations.
[2] Sales by a producer to an affiliated consumer for immediate use are not included with "Sold" but with "Used."
[3] Figure withheld to avoid disclosure of individual company operations.
[4] A plant producing more than 1 grade is counted but once in arriving at total.

REVIEW BY STATES

California.—Johns-Manville Products Corp., 22 East 40th Street, New York 16, N. Y., produced magnesium carbonate from purchased magnesium hydroxide at Redwood City, Calif., for use in 85-percent magnesia insulation. Kaiser Aluminum & Chemical Corp., Kaiser Building, Oakland, Calif., operated its magnesia-from-sea-water plant at Moss Landing, producing refractory and caustic-calcined magnesias. Marine Magnesium Products Corp. became Marine Magnesium Products Div., Merck and Co., Inc. on February 28, 1951. The plant at South San Francisco continued to produce precipitated magnesium carbonate, magnesium hydroxide, and specialty magnesias, using lime, dolomite, and sea-water bitterns as raw materials. Pabco Products, Inc., 1550 Powell Street, Emeryville 8, Calif., produced magnesium carbonate from purchased magnesium hydroxide and magnesia, for use in 85-percent magnesia insulation. Westvaco Chemical Division, Food Machinery & Chemical Corp., 161 East 42d Street, New York 17, N. Y., produced a small quantity of magnesite from its Western mine near Livermore, produced refractory and caustic-calcined magnesia from sea-water bitterns and dolomite at Newark, and recovered magnesium chloride from sea-water bitterns at Chula Vista.

Illinois.—Johns-Manville Products Corp., 22 East 40th Street, New York 16, N. Y., produced precipitated magnesium carbonate from purchased dolomite by the Pattinson process at its Waukegan, Ill., plant for use in 85-percent magnesia insulation.

Michigan.—The Dow Chemical Co., Midland, Mich., produced magnesium chloride and epsom salt from well brines and dolomite at Midland and in a new plant at Ludington, Mich. Michigan Chemical Corp., St. Louis, Mich., produced magnesium carbonate and magnesia from well brines and dolomite. The Morton Salt Co., 120

Digitized by Google

South LaSalle St., Chicago 4, Ill., produced precipitated magnesium carbonate from well brines at its Manistee, Mich., plant. Standard Lime & Stone Co., 2000 First National Bank Building, Baltimore 3, Md., produced refractory-grade magnesia from well brines and lime at its plant at Manistee.

Nevada.—Basic Refractories, Inc., 845 Hanna Building, Cleveland, Ohio, produced magnesite and brucite at its operation near Gabbs, Nev. Part of this material was processed into a line of refractories at its Maple Grove, Ohio, plant; the balance was calcined to produce refractory magnesia in a new plant at Gabbs that began production during 1951.

Sierra Magnesite Co., Box 8–A, Newark, Calif., produced magnesite from its Segerstrom mine near Gabbs, Nev. The Standard Slag Co., 1200 Wick Building, Youngstown, Ohio, produced magnesite from its mine near Gabbs, Nev., and shipped raw magnesite and caustic-calcined magnesia.

New Jersey.—The J. T. Baker Chemical Co., Phillipsburg, N. J., produced a line of high-purity magnesium compounds from purchased magnesium carbonate. Johns-Manville Products Corp., produced precipitated magnesium carbonate by the Pattinson process at its Manville plant for use in 85-percent magnesia insulation. Northwest Magnesite Co., 1922 Farmers National Bank Building, Pittsburgh 22, Pa., continued to recover refractory-grade magnesia from sea water and dolomite at its Cape May, N. J., plant.

Ohio.—The Diamond Alkali Co., 200 Union Commerce Building, Cleveland, Ohio, produced refractory magnesia from dolomite at Fairport.

Pennsylvania.—Keasbey & Mattison Co., Ambler, Pa., and the Philip Carey Mfg. Co., Cincinnati, Ohio (plant at Plymouth Meeting, Pa.), produced magnesia and magnesium carbonate for use in 85-percent magnesia insulation from raw dolomite. The Ehret Magnesia Mfg. Co., Valley Forge, Pa., produced magnesium carbonate for magnesia pipe and boiler covering. During the year dolomite was replaced by sea-water magnesia as the raw material used in manufacture.

Texas.—The Dow Chemical Co., at Freeport, Tex., recovered magnesium chloride from raw sea water as an intermediate in the production of magnesium metal. It also produced some magnesia.

Washington.—The Laucks Chemical Co., 1008 Western Ave., Seattle 4, Wash., produced epsom salt, by solar evaporation, from a natural deposit near Tonasket. Northwest Magnesite Co., 1922 Farmers Bank Building, Pittsburgh 22, Pa., the largest producer of natural magnesite in the United States, produced refractory magnesia near Chewelah.

Digitized by Google

West Virginia.—The Standard Lime & Stone Co., 2000 First National Bank Building, Baltimore 3, Md., produced a refractory magnesia from dolomite at its Millville, W. Va., plant.

PRICES

According to quotations in E&MJ Metal and Mineral Markets, the price of dead-burned grain magnesite per ton, carlots, f. o. b. Chewelah, Wash., remained unchanged in 1951 at $36.30 in bulk and $41.80 in bags. The Westvaco Chemical Division of Food Machinery & Chemical Corp. increased the price of its kiln-run 90-percent sea-water periclase from $50.50 per ton, carlots, bulk, f. o. b. Newark, Calif., to $55.00 per ton, effective January 1, 1951, where it remained for the rest of 1951. Powdered caustic-calcined magnesite in bags, carlots, f. o. b. California, remained at $75 per ton throughout the year.

According to quotations in the Oil, Paint and Drug Reporter, prices on the magnesium compounds listed below remained constant throughout the year. Espom salt, technical, bags, carlots, f. o. b. works, was quoted at $2.15 per 100 pounds. Technical-grade calcined magnesia, cartons, f. o. b. works, was quoted at 32 to 34¾ cents per pound; synthetic, rubber grade, cartons, f. o. b. works, at 31 cents per pound; U. S. P. light, cartons, at 34 to 36 cents per pound; and U. S. P. heavy, barrels, at 36 to 38 cents per pound. Magnesium carbonate, technical-grade, bags, carlots, freight equalized, was quoted at 9½ cents per pound; U. S. P. grade, at 11¼ cents per pound. Magnesium carbonate is quoted freight allowed to New Jersey (except to Atlantic, Burlington, Cape May, Cumberland, Gloucester, Ocean, and Salem Counties) and to Philadelphia County, Pa. Freight is equalized with New York City on all other destinations. Magnesium chloride, flake, barrels, carlots, f. o. b. works, was $45.00 per ton. Magnesium hydroxide, medicinal grade, was 29 to 30 cents per pound.

FOREIGN TRADE[1]

The greatly increased domestic demand for refractory magnesia accounted for an increase in imports of more than 100 percent in 1951 as compared with 1950, from 14,120 short tons to 28,785. Imports from Austria dropped slightly; those from Canada and Italy increased sharply; and imports were received from Brazil, Germany, Norway, and the United Kingdom, not previously listed.

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

TECHNOLOGY

A new precision self-setting process for the manufacture of 85-percent magnesia insulation is said to result in a product with a lower conductivity factor, higher strength-weight ratio, and closer tolerances than can be produced by the filter-mold process.[2] A specially prepared pure magnesium oxide refractory was developed to withstand the 2100° C. furnace temperature of the new Daniels or Wisconsin thermal process of nitrogen fixation.[3] The use of magnesite brick or monolithic magnesite cupola linings was reported to result in the production of low-sulfur iron suitable for making new nodular or ductile-type irons.[4] The operation of the magnesia-base sulfite process at the Weyerhaeuser Timber Co., Longview, Wash., mill was described and illustrated with flow diagrams.[5] The chemistry and operations of sea-water magnesia recovery plants in England were described.[6] The U. S. Geological Survey published a report on the magnesium-mineral resources of the Currant Creek District, Nev.[7] Numerous other technical articles on magnesium compounds appeared during the year.[8]

WORLD REVIEW

World magnesite production reached an estimated 3,800,000 metric tons in 1951, 27 percent more than in 1950, as shown in table 7.

TABLE 7.—World production of magnesite, 1947–51, by countries,[1] in metric tons

[1] Unless otherwise stated, quantities in this table represent crude magnesite mined. In addition to countries listed, magnesite is also produced in Canada, China, Korea, and U. S. S. R., but data on tonnage of output are not available; estimates by senior author of chapter included in total.
The Canadian production was actually magnesitic dolomite and brucite, valued as follows: 1947: C$1,167,584; 1948: C$1,587,709; beginning in 1949, value includes magnesium metal: 1949: C$1,536,200; 1950: C$1,717,879 (revised); 1951: C$2,451,778.
[2] Revised figure.
[3] Data not available; estimate by senior author of chapter included in total.
[4] Estimate.
[5] Figure withheld to avoid disclosure of individual company operation; included in total.
[6] World totals revised to include higher undisclosed estimates on U. S. S. R.

Austria.—The 1951 crude magnesite production of 664,296 metric tons, 22 percent greater than the previous year, was derived from the mines and occupation zones shown in table 8.

Finland.—A magnesite deposit, reported to be the largest in Europe, has been discovered in Lapland. The grade of the ore is said to average 90 percent $MgCO_3$.[9]

Greece.—Magnesite ore exports in 1951 were 17,630 tons, valued at US$200,182, more than 2½ times the 1950 exports. Output of caustic-calcined magnesite was 20,372 tons in 1951, with exports amounting to 17,687 tons and valued at US$694,992.[10]

Italy.—Output of magnesite in Italy declined from a peak of 13,686 metric tons in 1942 to 200 metric tons in 1950, and rose slightly to 246 metric tons in 1951. Recent activities at the largest operating mine (the Querceto mine in the Val d'Elsa) have been limited to sorting ore from surface workings. The Societa Magnesite Val d'Elsa proposed to implement a program to increase output to 3,000 or 4,000 tons per year. This level of output would supply one-third of Italy's requirements of crude magnesite, currently supplied by imports from

Manganese

By Edgar J. Gealy and Gilbert L. DeHuff

GENERAL SUMMARY

IMPORTS of manganese ore into the United States dropped slightly in 1951 and failed to pace the sharp increase in consumption. Receipts, although lower than those of 1950, exceeded those for 1946, to make 1951 the second highest manganese-ore import year on record. None was received from the Soviet Union.

Receipts from India were reduced to 90 percent of the 1950 volume but supplied 32 percent of the total, and were large enough to maintain that country's position as the supplier of the largest quantity of manganese ore to the United States. Indian imports, in addition to dropping in quantity, decreased slightly in grade, averaging 47.1 percent manganese. This drop in quantity and grade of imports occurred even though the total production of ore in India was much higher than in 1950. This was attributed, in part, to the unusually heavy purchases of Indian ore by Japanese industry, which was buying to replenish stocks as well as to provide for reviving steel production.

Gold Coast replaced the Union of South Africa as the second largest supplier in 1951 and furnished 20 percent of the total. Although total imports from Gold Coast increased 10 percent over 1950, the tonnage of battery- and chemical-grade ores decreased 12 percent. Gold Coast supplies the bulk of the natural oxide ores which are suitable for the manufacture of dry-cell batteries and for many chemical products, including hydroquinone, permanganates, fluxes, dyes, and dye intermediates. Although some chemical consumers can use ores from other sources, the virtual lack of other substantial sources of battery-grade material assigns strategic importance to this material.

The Union of South Africa showed the largest decline from 1950 of any of the major United States sources of manganese ore and fell from 26 percent in 1950 to 20 percent of the 1951 import total. This loss of ore from the Union more than accounted for the reduction in total imports from 1950 and was viewed with apprehension by United States consumers and Government alike. The shortage of rail facilities and dock facilities has been cited as the main deterrent to increased export of ore, but a growing feeling for conservation of natural resources in the Union appeared to be gaining headway.

Cuba assumed new importance as a supplier of manganese ore by substantially increasing exports to the United States for the third straight year. General imports in 1951 were 1.5 times as great as in 1950, 2.4 times as great as in 1949, and 4.5 times as great as in 1948, representing a remarkable recovery in response to higher prices and a firm market. Indications were that Cuban mine production was still expanding and could support an even higher export level in 1952.

Digitized by Google

Mexican production and exports of manganese ore to the United States revived from 1950 under the impetus of higher prices. The uncertainty of rail facilities still plagued producers and United States importers, and further expansion of Mexican production appeared possible in the future under more favorable transportation conditions.

With elimination of receipts from the U. S. S. R., owing to the Soviet embargo on movement of manganese ore to the United States, and the reduced supplies available from such major sources as India and the Union of South Africa, a much greater degree of dependence was placed on the smaller producing areas of the world. Whereas the tonnages from the first five supplying countries in 1950 totaled almost 240,000 short tons less than in 1951, the total loss was held to 66,000 tons because of increased imports from new and minor sources.

TABLE 1.—Salient statistics of manganese in the United States, 1947–51, gross weight in short tons

	1947	1948	1949	1950	1951
Manganese ore (35 percent or more Mn):					
Mine shipments:					
Metallurgical ore	125,428	119,828	110,928	122,944	95,255

Domestic production	614,626	647,617	577,345	719,680	791,260
Imports for consumption	81,307	98,220	65,014	109,948	119,764
Exports	20,168	19,696	6,627	580	633
Consumption	662,214	670,774	617,745	774,852	883,841
Spiegeleisen:					
Domestic production	134,329	112,610	78,167	42,375	77,017
Imports for consumption			1,737	8,595	
Exports	305	51		363	85
Consumption	120,019	102,392	75,841	76,280	80,556

Increased consumption of manganese ores, coincidental with reduced receipts, resulted in a severe drain on the stocks of ore held at ferroalloy furnaces. Alloy-producing companies ended 1950 with approximately 720,000 short tons of ore on hand, and this inventory was reduced at a rate of 25 to 30 thousand tons a month during 1951. Imports were erratic, and some consumers were reduced to dangerously low stocks. The demand for manganese alloys continued at a high level, and any interruption in alloy production could have had a serious effect on steel production. Under the authority of the Defense Production Act of 1950, the Defense Minerals Administration issued Mineral Order MO–2 covering manganese ore, effective April 1, 1951. The purpose of this order was to conserve and provide for the distribution of manganese ore so as best to serve the interest of national defense and essential civilian production. The order provided that no person should deliver manganese ore or accept delivery of manganese ore except in accordance with the terms of an allocation authorization issued by the Defense Minerals Administration. Allocation restrictions were limited to metallurgical and chemical-grade ore, since the battery industry is restricted naturally to the use of specific grades of ore.

Digitized by Google

On June 27 General Services Administration was authorized to purchase manganese ore of domestic origin which was amenable to concentration to purchase specifications for the National Strategic Stockpile. On July 19 three depots for such purchases were opened—at Butte and Philipsburg, Mont., and Deming, N. Mex. Prices and grades of ore accepted at each depot varied with the type of ore available in the areas covered. At Butte prices started at $6.05 per long dry ton of ore with 12 percent manganese content and went up to $40.42 for ore containing 30 percent Mn; at Philipsburg the range was from $6.43 at 15 percent Mn to $34.81 at 30 percent Mn; and at Deming the range was from $6.10 at 15 percent to $76.00 at 40 percent. The Montana depots accepted only ore in which at least 90 percent of the contained manganese was present as a carbonate. The Deming depot imposed no restrictions as to the type of ore to be accepted other than it be amenable to concentration to the required specifications; for ore deliveries exceeding 200 long tons a month, payments were adjusted on the basis of laboratory-determined recoverability.

On August 28 the functions of Defense Minerals Administration were split between Defense Minerals Exploration Administration and Defense Materials Procurement Agency. Assistance for exploration of areas geologically favorable for the discovery of new reserves was made the function of DMEA, while development loans and other assistance, along with ore purchasing and allocation of ores, became the function of DMPA.

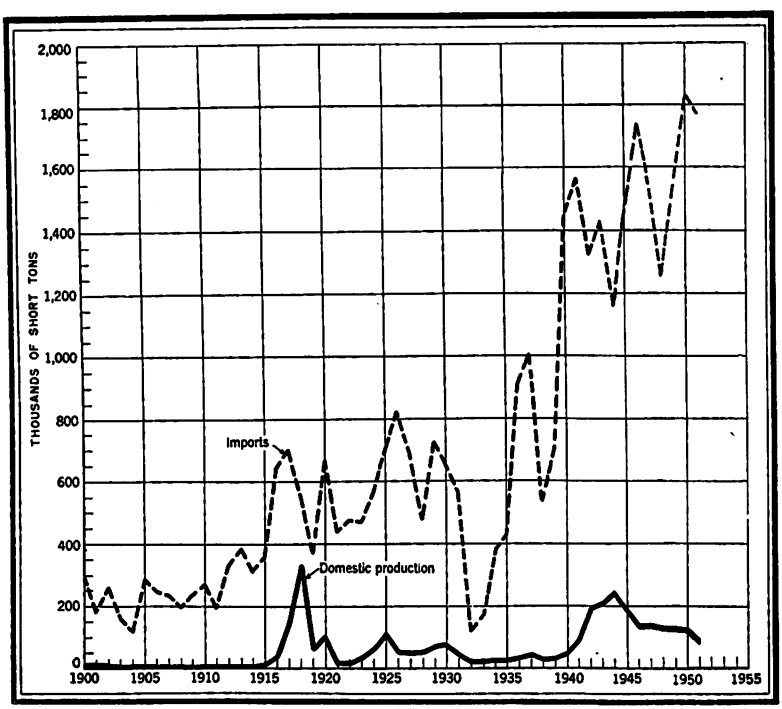

FIGURE 1.—General imports and domestic production (mine shipments) of manganese ore. 1900–51.

Bureau of Mines manganese research made considerable progress in 1951. The pilot plant at Pittsburgh for extracting manganese from open-hearth slags was completed in part, and test runs were made in the experimental blast furnace, using open-hearth slags and ore from Aroostook County, Maine; there were indications that these materials were amenable to blast-furnace smelting with coke to recover the manganese in a high-phosphorus spiegeleisen. The converter to investigate the oxidation step of the proposed process was being constructed at the end of 1951. Work on open-hearth slags and Aroostook ore at College Park, Md., consisted of applying standard ore-dressing techniques as well as various chemical and metallurgical methods to determine the most likely field of research. By the end of 1951 it was determined that mechanical means of beneficiation were unsuccessful and that the best results probably could be obtained from some form of an ammonium carbonate leaching process.

A cooperative agreement between the Bureau of Mines and the American Iron and Steel Institute, which provided assistance in the investigation of open-hearth slags and made larger funds and additional technical aid available, was signed on May 1.

Plans were completed for the 50-ton-a-day pilot plant at Boulder City, Nev., and several portions of the plant were completed and tested. Meanwhile laboratory work of gathering information and data for use in the plant operation continued. When completed, the pilot plant would investigate beneficiation of lowgrade ores from Artillery Peak and other sources.

DOMESTIC PRODUCTION

Table 2 shows the various types of manganiferous materials shipped by domestic producers 1947 to 1951.

TABLE 2.—Manganiferous raw materials shipped by producers in the United States, 1947–51, in short tons

Year	Metallurgical ore				Battery ore (25 percent or more Mn)	Miscellaneous ore	
	Manganese ore (35 percent or more Mn)	Ferruginous manganese ore (10 to 35 percent Mn)	Manganiferous iron ore (5 to 10 percent Mn)	Manganiferous zinc residuum		35 percent or more Mn	10 to 35 percent Mn
1947	125,428	128,562	1,044,961	227,547	6,189	10	832
1948	119,328	139,580	1,198,523	291,383	10,845	427	2,462
1949	110,928	24,885	1,052,231	158,902	14,983	224	1,279
1950	122,944	115,269	972,328	183,842	11,507	----------	----------
1951	95,255	106,203	1,117,761	267,751	9,752	----------	----------

Shipments of various grades of manganese-bearing ores during the last 5 years are given by States in tables 3 to 5. In addition, battery ores containing 35 percent or more manganese were produced in Montana and Nevada, and manganiferous zinc residuum was produced from New Jersey zinc ores.

MINING BY STATES

Arizona.—A. F. Denison shipped manganese ore containing (natural) 52 percent manganese from Coconino County, U. S. Manganese shipped a (natural) 40-percent ore from Gila County, and Business Service, Inc., shipped a (natural) 37-percent ore. In addition, some shipments of ferruginous ore of (natural) 28-percent manganese were made.

Arkansas.—Denison Manganese Co. shipped a (natural) 37-percent ore and Westmoreland Manganese Co. a (natural) 50-percent ore from Independence County. Ferruginous ore of (natural) 27 percent manganese also was shipped from Independence County.

Minnesota.—The Hanna Coal & Ore Corp., Oliver Mining Co., and Pickands, Mather & Co. shipped manganiferous iron ore from Crow Wing and St. Louis Counties averaging (natural) 5.8 percent manganese. Ferruginous ore containing (natural) 12.2 percent manganese was also shipped from Crow Wing County.

[1] All metallurgical ores except shipments of battery ores as follows: Montana, 2 shippers, 9,482 gross weight, 4,074 manganese content; and Nevada, 1 shipper, 270 gross weight, 151 manganese content. All this battery ore contained 35 percent or more manganese (natural).
[2] Containing 35 percent or more manganese (natural).
[3] Not available: estimate included in total.
[4] Estimate.
[5] Containing 10 to 35 percent manganese (natural).
[6] Containing 5 to 10 percent manganese (natural).
[7] Figure withheld to avoid disclosure of individual company operations.

Montana.—Montana continued to be the leading manganese-ore-producing State, with 96 percent of the total domestic output. This position was due principally to the Anaconda Copper Mining Co., which processes crude ore from the Emma and Butte Hill mines in Silver Bow County into nodules containing (dry) 58.5 percent manganese. The Trout Mining Division of the American Machine & Metals, Inc., shipped ferruginous ore containing (natural) 23.8 percent manganese. Trout Mining Division, along with Taylor-Knapp Co., shipped 9,482 short tons of battery-grade manganese ore averaging (natural) 43 percent manganese or 67 percent manganese dioxide.

Nevada.—Western Electrochemical Co. shipped battery-grade ore containing (dried) 56 percent manganese from a new plant in Henderson, Nev. Combined Metals Reduction Co. shipped metallurgical ore containing (natural) 46 percent manganese from Henderson, processed from low-grade ores from Lincoln County. Two other companies produced ferruginous ore averaging (natural) 28 percent manganese.

New Mexico.—The Deming purchase depot accepted the first shipment of ore late in November 1951, and deliveries for the balance of the year indicated a stimulation of small mines in the area. Two operators shipped ore containing (natural) 44 percent manganese,

Digitized by Google

5 operators shipped ferruginous ore containing (natural) 10 percent manganese, and 1 producer shipped manganiferous ore averaging 9.8 percent manganese. The Luck Mining & Construction Co. produced the major portion of the ferruginous ore from the Boston Hill mine in Grant County.

Utah.—One producer shipped ferruginous ore containing (natural) 30 percent manganese.

CONSUMPTION AND STOCKS

The continuing expansion of steel production during 1951 created a heavy demand for manganese alloys and manganese ores, with the overall consumption of ores increasing 11 percent over 1950. In 1951, as in 1950, domestic sources supplied 7 percent of the ore while foreign sources supplied 93 percent as compared with 10 percent and 90 percent respectively in 1949. Dry-cell batteries consumed 2.5 percent of the total and chemicals consumed 1.5 percent, the remaining 96 percent being consumed in metals industries. The stocks of ore held by industry showed an alarming reduction from 826,757 short tons to 545,769 tons, a 34-percent decrease. In addition to decreasing in tonnage, inventories dropped in grade, particularly those held by alloy producers. As the stocks decreased, a smaller proportion of the higher grade ores was available, which was reflected in the drop in the grade of ferromanganese produced in 1951 as compared with 1950.

TABLE 7.—Apparent consumption of manganiferous raw materials in the United States in 1951

	Ore containing 35 percent or more Mn		Ore and residuum containing 10 to 35 percent Mn		Ore containing 5 to 10 percent Mn	
	Short tons	Mn content (percent)	Short	Mn content (percent)	Short tons	Mn content (percent)
Domestic shipments	105,007	56.34	373,954	13.00	1,117,761	5.78
Imports for consumption	1,902,859	46.36	175,261	26.62	----------	----------
Total available for consumption	2,007,866	46.89	549,215	17.28	1,117,761	5.78

Table 8 shows the actual tonnages of manganese ore containing (natural) 35 percent or more manganese and manganese alloys consumed during 1950 and 1951 by the product for which consumed, together with consumers' stocks at the end of 1951.

[1] Excluding Government stocks.
[2] Data not available.
[3] Includes only that part of castings made by companies that also produce steel ingots.
[4] Excludes companies that produce both steel castings and steel ingots.
[5] Data for 1950 not available; 1949 figures carried over to show approximate magnitude of consumption.
[6] The greater part of the consumption of ore was used in the manufacture of ferromanganese and silicomanganese. Combining consumption of ore with that of ferromanganese and silicomanganese would result in duplication.
[7] Excludes small tonnages of dealers' stocks.
[8] Excludes small tonnages of producers' stocks.

In 1951 the consumption of manganese as ferroalloys and directly charged ore was 13.2 pounds per short ton of steel manufactured compared to 13.6 pounds in 1950 and 13.2 in 1949. Of the manganese used per ton of steel in 1951, 11.9 pounds was in the form of ferromanganese, 1.0 pound silicomanganese, 0.25 pound spiegeleisen, and 0.05 pound ore, metal, and miscellaneous alloys. These data apply to the consumption of manganese in the manufacture of steel ingots and that part of steel castings manufactured by companies that also produce steel ingots. The companies reporting in this part of the survey are those reporting production of ingots and castings to the American Iron and Steel Institute. Adding the manganese consumed by those companies producing castings only, the total figure becomes 13.95 pounds, broken down to 12.5 pounds as ferromanganese 1.1 pounds as silicomanganese, 0.25 pound as spiegeleisen, and 0.1 pound as metal, ore, briquets, and miscellaneous alloys.

[1] Number of domestic plants making ferromanganese: 1950, 10; 1951, 14.
[2] Estimated.
[3] Number of domestic plants making spiegeleisen: 1950, 4; 1951, 5.
[4] No spiegeleisen produced from foreign ore.

Electrolytic Manganese.—The Electro Manganese Corp., Knoxville, Tenn., was the only producer of electrolytic manganese in 1951.

Ferromanganese.—Ferromanganese production in the United States increased 10 percent to 791,260 short tons in 1951 compared with 719,680 tons in 1950. The following plants were active producers during the year: Anaconda Copper Mining Co., Anaconda and Black Eagle, Mont.; Bethlehem Steel Co., Johnstown, Pa.; The Electro Metallurgical Co., division of Union Carbide & Carbon Corp., Alloy, W. Va., Ashtabula, Ohio, and Niagara Falls, N. Y.; E. J. Lavino & Co., Sheridan, Pa., and Reusens, Va.; New Jersey Zinc Co., Palmerton, Pa.; Tennessee Coal, Iron & Railroad Co., Ensley, Ala.; United States Steel Co., Clairton, Duquesne, and Etna, Pa. Electro Metallurgical Co. and Anaconda Copper Mining Co. produced in electric furnaces, and New Jersey Zinc Co. produced by an aluminothermic reduction; the remaining companies produced ferromanganese in blast furnaces. Manganese ore consumed in the manufacture of ferromanganese totaled 1,527,420 short tons in 1951 of which 7 percent was of domestic

Digitized by Google

origin and 93 percent foreign, the same ratio as in 1950. In spite of the lower average grade of ore used in the production of ferromanganese, the recovery of manganese from the ore increased to 86.2 percent compared with 83.6 percent in 1950, 83.3 percent in 1949 and 84.6 in 1948. Shipments from producing furnaces increased 9 percent in quantity and 5 percent in value from 1950.

Silicomanganese.—The Bureau of Mines first published data on the consumption of manganese alloys for 1941, at which time the consumption of silicomanganese was 8 percent of ferromanganese. By 1951 silicomanganese consumption had increased to 10.5 percent of ferromanganese. Silicomanganese is used by the steel industry as a furnace block, as a deoxidizer, and for manganese additions. Although both silicon and manganese are good deoxidizers, silicon has the greater affinity for oxygen and thus protects the manganese. This property of silicomanganese in addition to the relatively low carbon content of the alloy makes it particularly useful for manganese additions to low carbon or high manganese steels.

Spiegeleisen.—United States production of spiegeleisen increased 82 percent in 1951 to 77,017 short tons from 42,375 tons in 1950. Shipments from spiegeleisen furnaces increased 21 percent in quantity and 39 percent in value. Four companies produced spiegeleisen at five plants in 1951; Inland Steel Co., East Chicago, Ind.; New Jersey Zinc Co., Palmerton, Pa.; Tennessee Coal, Iron & Railroad Co., Ensley, Ala.; and United States Steel Co., Clairton and Etna, Pa. Virtually all of the material used in the manufacture of spiegeleisen was of domestic origin.

TABLE 13.—Spiegeleisen produced and shipped in the United States, 1946–51

Year	Produced (short tons)	Shipped from furnaces		Year	Produced (short tons)	Shipped from furnaces	
		Short tons	Value			Short tons	Value
1946	111,696	114,982	$3,793,673	1949	78,167	53,888	$2,972,653
1947	134,329	124,517	4,980,030	1950	42,375	65,163	3,875,823
948	112,610	108,960	5,261,650	1951	77,017	79,168	5,368,989

Manganiferous Pig Iron.—Pig-iron furnaces consumed 1,132,409 short tons of manganese-bearing ores containing (natural) over 5 percent manganese in 1951. Domestic ore used totaled 943,928 tons and foreign ore 188,481 tons. Of the domestic material used, 829,575 tons contained (natural) 5 to 10 percent manganese, 108,423 tons 10 to 35 percent manganese, and 5,930 tons over 35 percent manganese. Of the foreign material used, none contained below 10-percent manganese, 87,457 tons contained (natural) 10 to 35 percent manganese, and 101,024 tons contained over 35 percent manganese.

Battery and Miscellaneous Industries.—Manufacturers of dry cell batteries used 44,127 short tons of manganese ore in 1951, an increase of 7 percent over 1950; of this total 3,191 tons was domestic and 40,936 tons foreign ore. Chemical plants used 27,266 tons, of which 4,733 tons was domestic and 22,533 tons foreign ore. All ore used contained (natural) over 35 percent manganese. The principal use of chemical ore is in the manufacture of dyes, manganese sulfate for fertilizer, hydroquinone, and permanganates. Manganese ore for battery use should have a high content of available oxygen, with a minimum of iron and virtually no arsenic, nickel, copper, cobalt, or other metals electronegative to zinc. Preferably, battery-grade manganese ore should be poorly crystallized and consist of the gamma

Digitized by Google

oxide. Ore for chemical use usually is predominantly pyrolusite. Domestic ore used for chemicals is chiefly a semireduced oxide material soluble in sulfuric acid.

TABLE 14.—Foreign ferruginous manganese ore and manganiferous iron ore consumed in the United States, 1947–51, in short tons

Source of ore	Ferruginous manganese ore					Manganiferous iron ore

PRICES

Manganese Ore.—Prices of manganese ore, containing 48 percent manganese, as quoted by E&MJ Metal and Mineral Markets, ranged from 92 to 96 cents per long-ton unit, c. i. f., United States ports, duty to account of buyer, at the beginning of 1951, to $1.20 to $1.25 per unit at the end of the year. These prices were quoted for current business while long-term contracts ranged from about 80 cents at the beginning of 1951 to 90 to 95 cents per unit at the end of the year, c. i. f., United States ports, duty paid, on 48-percent manganese ore.[1] Foreign chemical ore increased about $5 per ton for 80 and 85 percent manganese dioxide to $65 to $70 and $75 to $80 respectively. Domestic material, 70 to 72 percent manganese dioxide was steady at $45 to $50 f. o. b. mines. Duty remained at one fourth cent per pound of contained manganese; Cuba and the Republic of the Philippines material entered exempt from duty.

Manganese Alloys.—The average value, f. o. b. producer's furnaces, for ferromanganese shipped during 1951 was $153.75 per short ton compared with $158.65 in 1950. According to Iron Age, the selling price of ferromanganese in eastern centers in carlots was $185.24 per long ton in January, rose to $186.25 in February, and held constant through the remainder of the year with an average price of $186.16. The average value for spiegeleisen was $67.82 per short ton, f. o. b. domestic furnaces, in 1951 as compared with $59.48 for 1950; the quoted price on a long-ton basis, as given by Iron Age, was $75 throughout 1951. These materials were under price control by the Office of Price Stabilization from almost the beginning of 1951. The decrease in value of ferromanganese shipped from furnaces was due to the drop in the grade of the ferromanganese to lower than 78 percent manganese, at which point price penalties were invoked.

[1] The long-ton unit upon which the price of manganese ore is based is 1 percent of a long ton (22.4 pounds) of contained manganese. Prices of chemical ore are given on a per ton basis, with a minimum requirement of manganese dioxide.

FOREIGN TRADE[2]

Imports of all grades of manganese ore (battery, chemical, and metallurgical) are shown by countries in table 15. These data include general imports of battery-grade ore totaling 68,282 short tons in 1951: 55,571 tons originating in Gold Coast, 5,294 tons in French Morocco, 4,256 tons in Cuba, 1,436 tons in India, 1,120 tons in Angola, 560 tons in Chile, and 45 tons in Mexico. This ore averaged 54.7 percent manganese or 86.8 percent manganese dioxide, and it is known that these imports include some receipts of chemical ore. Imports for consumption of battery ore totaled 65,685 short tons valued at $2,446,393 or $37.24 per short ton f. o. b., foreign ports. Of this total, Gold Coast supplied 52,974 tons valued at $1,981,090; French Morocco, 5,294 tons at $236,113; Cuba, 4,256 tons at $112,419; India, 1,436 tons at $47,511; Angola, 1,120 tons at $50,000; Chile, 560 tons at $18,240; and Mexico, 45 tons at $1,020.

Imports for consumption of ferromanganese increased 8.9 percent in 1951 over 1950 to 119,764 short tons while the value increased 23.5 percent to $20,046,139. Exports of manganese ore and concentrates totaled 8,030 short tons valued at $465,897.

[2] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

WORLD REVIEW

World production of manganese ore from 1946 to 1951 is shown in table 19, insofar as the statistics are available, with average manganese content indicated where possible. These data are from official statistics of the countries, supplemented by information from semi-official and other sources.

TABLE 19.—World production of manganese ore, 1946–51, by countries, in metric tons [1]

[1] In addition to countries listed, Argentina, Bulgaria, and Korea have produced manganese ore; data of output are not available, but estimates for them are included in the totals. Czechoslovakia, Germany, and Northern Rhodesia report production of manganese ore, but it is believed that the product so reported averages less than 30 percent Mn and therefore would be considered ferruginous manganese ore under the classification used in this report, and the output not included in this table.

Brazil.—Three new deposits of manganese ore discovered recently were in production. One deposit is near Sao Felipe, State of Espirito Santo, another at Chapadao, Guacui in the same State, and the third is at Betim, State of Minas Gerais.[3] United States Steel Corp. was granted the exploration rights to the manganese deposit at Urucum and negotiated a loan from the Export-Import Bank for development of the property.[4] Following the grant of the exploration rights and the negotiation for the loan, it was found that the arrangements were apparently contrary to Brazilian laws on concessions and on operations of foreign companies. This matter was then placed in the Brazilian courts, and activity stopped. Although development of the Urucum deposit was still of interest, it appeared that some new arrangements would have to be made in the future. Bethlehem Steel Co. was interested in developing manganese deposits at Amapa, which would require more development than Urucum, owing to their geographic location.

Chile.—The Fabrica Nacional de Carburo y Metalurgica was operating a flotation mill and a ferromanganese plant at Nos for the production of the alloy from the manganese ores of the Corral Quemada mines near Coquimbo. Smelting was done in electric furnaces, presumably with hydroelectric power.[5] This company intended to enlarge its operations with an additional ferromanganese installation at Huachipato.

Costa Rica.—Small shipments of manganese ore have been made from a concession in Guanacaste Province operated by Minerals Operating Co., a subsidiary of the Latin American Resources Development.[6]

French Morocco.—To facilitate moving manganese ore mined from the deposits south of the Atlas Mountains to the port of Marrakech, an aerial tramway was being constructed over a distance of 28 kilometers. This was expected to eliminate the most difficult part of the transportation, the cost of which represented nearly two-thirds of the export selling price.[7]

Greece.—The Economic Cooperation Administration authorities were to finance attempts to speed production of Greek manganese ore by contributing about 70 percent of the cost of exploration, the loans to be repaid by deliveries of ore to the National (United States) Strategic Stockpile.[8]

India.—The Shivrajpur Syndicate, one of India's largest producers, entered into contracts for about 75 percent of its production for the next 3 years and planned to spend $100,000 to expand production facilities.[9] Indian officials announced that the export quota for high-grade ore was 800,000 long tons, with no limit on low-grade ore.[10]

Philippines.—The Luzon Stevedoring Co. took over the operations of the Palawan Mining Co. in Busuanga, and a large output was expected from this prominent prewar producer. Current high prices for manganese ore have stimulated mining, and about 2,000 tons a

month is being shipped from Bohol, now the most important producing area in the Philippines.[11]

South-West Africa.—A report was given to the South African Minerals Corp. by a consulting engineer on the recent discovery northeast of Okahandja in the Otjiqarongo field. The report stated that the discovery was of great value and suggested an annual production rate of 70,000 tons. The prospected portion is 20 miles long and varies in width from 10 to 150 feet. The deposit is about 210 miles from the port of Walvis Bay.[12] Later in 1951, South African Minerals announced an arrangement with U. S. Steel Corp. for regular shipments of manganese ore from properties in South-West Africa. It was indicated that this ore would be concentrated to about a 48-percent product.[13]

Mercury

By Helena M. Meyer and Gertrude N. Greenspoon

GENERAL SUMMARY

CONSUMPTION of 56,848 flasks of mercury, second only to the all-time annual peak established in 1945, was the outstanding feature of the mercury industry in 1951. Other features were the high though not record rate of imports, reversal in the downtrend in domestic production that followed the 61-year peak of 1943, and the top annual-average price for all time.

The completion and placing in operation in November of a new large chlorine and caustic-soda plant using mercury cells at Saltville, Va., was the chief reason for the record peacetime mercury consumption. The assurance that additional similar plants would begin to operate in 1952 indicated that withdrawals of mercury from new supply or stocks would continue large for another year at least. Except for chlorine and caustic-soda manufacture, the agricultural use of mercury made the most spectacular gain in 1951; most other uses took smaller quantities of mercury in 1951 than 1950.

Production of mercury in the United States did not rise in response to the high prices of 1951, as at the outset of World War II, despite seemingly similar stimulation. The history of price fluctuations in that war was fresh in producers' minds, and they sought some assurance as to price stability before they expanded production. Production did increase to 7,293 flasks (61 percent more than the 4,535 flasks in 1950), but the latter total was the smallest annual quantity, by a substantial margin, in 100 years. Except for 1950, the output in 1951 was the lowest since 1922. Output in the fourth quarter of 1951 was 3,270 flasks or 45 percent of the annual total.

Because world production capacity is adequate for known world needs and because the United States National Stockpile is more comfortably supplied with mercury than with most other strategic commodities, mercury was put low on the list for aid under the Defense Production Act. The Defense Minerals Administration decided that, under conditions prevailing in 1951, mercury was ineligible for production expansion assistance, that is, Government production loans, Government purchase contracts, and tax amortization benefits. It was decided, however, that exploration loans would be granted to properties that fulfilled established specifications. These loans were granted on a matching-funds principle, the Government meeting 75 percent and the operator 25 percent of costs.

Mercury prices were rising sharply as the year began, and quotations were $225 to $227 a flask at the end of January. The General Ceiling Price Regulation, approved by the Economic Stabilization Agency on January 26, provided that prices be held at not to exceed the highest level prevailing from December 19, 1950, to January 25, 1951, inclusive. This regulation established ceilings on an individual basis, and

TABLE 1.—Salient statistics of the mercury industry in the United States, 1942–46 (average) and 1947–51

[Flasks of 76 pounds]

	1942–46 (average)	1947	1948	1949	1950	1951
Production	39,315	23,244	14,388	9,030	4,535	7,293
Number of producing mines	110	37	20	23	16	47
Average price per flask: New York	$148.61	$83.74	$76.49	$79.46	$81.26	$210.13
Imports for consumption	37,762	13,008	31,951	103,141	56,080	47,860
Exports	685	884	526	577	447	241
Consumption	43,216	35,581	46,253	39,857	49,215	56,848

as most domestic producers had not sold metal during this period a problem was created. In such cases the Office of Price Stabilization was called upon to determine ceiling prices. On August 10 mercury was exempted from price control, along with some other strategic items, by General Overriding Regulation 9, Amendment 4. Quoted prices were at their lowest level of the year in the third quarter and

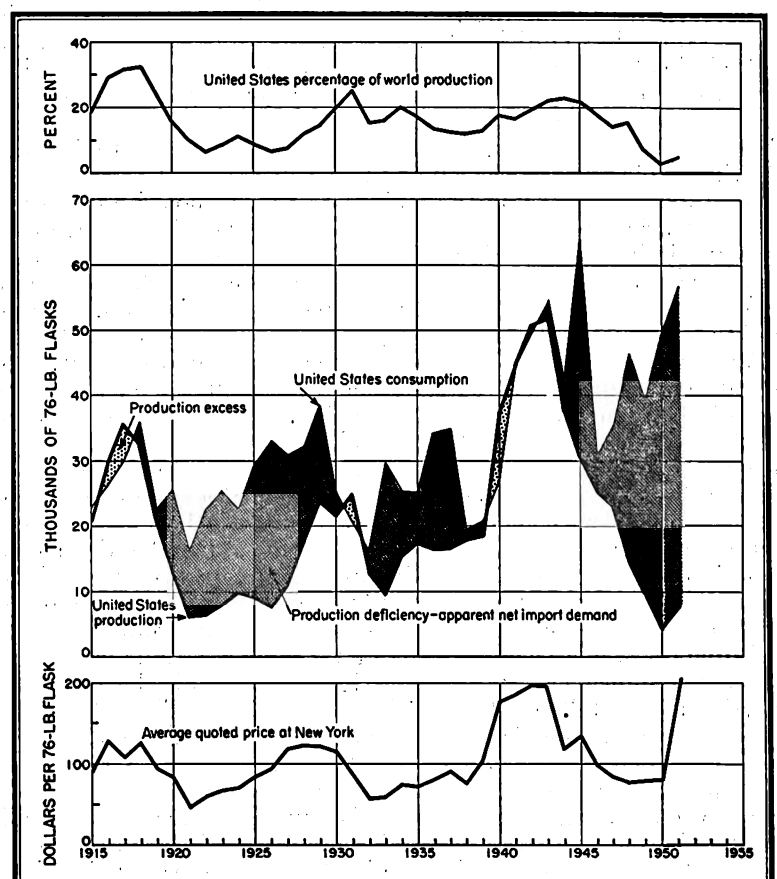

FIGURE 1.—Trends in production, consumption, and price of mercury, 1915–51.

Digitized by Google

advanced to the year's highest level in the final quarter. The average quotation for the year—$210 a flask—established a new annual peak. The previous record price of $196 in 1942 doubtless would have been exceeded in the early part of World War II, except for ceiling price limitations established by the Office of Price Administration. The development of adequate supplies of mercury during the war, however, resulted in the price falling far below ceiling limitations for many months before the war's end.

Imports (general) of mercury were 44,925 flasks—26 percent less than in 1950 and 54 percent less than in 1949—but were greater than in all earlier years except the war years 1945 and 1943. Metal moved into the United States during 1951 at a relatively uniform quarterly rate. The four chief suppliers—Italy, Spain, Yugoslavia, and Mexico, in order of importance—were the same as in 1950, although the positions of Italy and Spain were reversed. Of the 1951 total 39 percent came from Italy and 30 percent from Spain. Mercury came to the United States again in 1951 from countries that are normally importing areas; the metal possibly represented, in large part, mercury obtained for speculative purposes, following the start of Korean hostilities in June 1950, and reexported.

Mercury exports, always small, fell from 447 flasks in 1950 to 241 in 1951; reexports dropped from 886 flasks to 675 during the period.

Industrial stocks of 35,619 flasks in the hands of producers, consumers, and dealers at the beginning of the year were abnormally high, owing in large part to accumulation of metal for the Saltville, Va., chlorine plant. At the end of the year, the reduced inventories of 30,172 flasks no longer included metal held for the Saltville plant, which was then in operation, but included substantial quantities held for planned new installations at McIntosh and Muscle Shoals, Ala., and Plymouth, N. C.

DOMESTIC PRODUCTION

Production in the United States rose 61 percent in 1951, but this increase seemed large only by comparison with the 100-year record-low quantity in 1950; output in 1951 was less than in any other year

TABLE 2.—Mercury produced in the United States, 1948–51, by States

Year and State	Producing mines	Flasks of 76 pounds	Value [1]	Year and State	Producing mines	Flasks of 76 pounds	Value [1]
1948:				1950:			
Alaska	1	100	$7,649	California	14	3,850	$312,851
California	13	11,188	855,770	Nevada	1	680	55,257
Idaho	1	543	41,534	Oregon	1	5	406
Nevada	4	1,206	92,247				
Oregon	1	1,351	103,338	Total	16	4,535	368,514
Total	20	14,388	1,100,538	1951:			
1949:				Arizona and Texas	3	77	16,180
Alaska	1	100	7,946	California	27	4,282	899,777
California	15	4,493	357,014	Idaho	1	357	75,016

[1] Value calculated at average price at New York.

Digitized by Google

since 1922. The 1951 output supplied 13 percent of domestic consumption despite the all-time peak annual-average price. Evidently producers feared reversal of the rapid price gains and a possible precipitous slump. The ability of foreign producers to supply foreseeable mercury demand at more favorable costs for the short term, at least, deterred expansion of domestic production.

Most of the increase in output was in the final quarter, when 45 percent of the total was produced. Even at the expanded rate in October to December, however, output amounted to only 75 percent of the 1935–39 quarterly average and to only 28 percent of the quarterly rate in 1940–43, when output had responded to the rapid price gains of that period. If prices for mercury are "deflated" by changes in the Bureau of Labor Statistics general index for wholesale commodities, the peak 1951 price is reduced substantially. Actual and adjusted prices follow:

	Average annual prices (range)	
	Actual	*Adjusted*
1935–39	$71. 99 to $103. 94	$90 to $135
1940–43	176. 87 to 196. 35	225 to 199
1950	81. 26	50
1951	210. 13	116

TABLE 3.—Mercury produced in the United States, 1944–45, by months, and 1946–51, by quarters, in flasks of 76 pounds

Month	1944	1945	1946	1947	1948	1949	1950	1951
January	4,400	2,500						
February	3,800	2,700	5,550	6,100	5,300	1,440	1,700	880
March	3,800	3,000						
April	3,700	3,000						
May	3,400	3,300	7,000	5,700	3,600	1,460	1,010	1,400
June	3,000	3,000						
July	2,700	3,600						
August	2,500	3,300	6,500	5,850	3,150		1,100	1,600
September	2,500	2,050				6,980		
October	2,700	1,200						
November	2,300	1,350	6,150	5,550	2,050		630	3,270
December	2,500	1,600						
Total: Preliminary	37,300	30,600	25,200	23,200	14,100	9,880	4,440	7,150
Final	37,688	30,763	25,348	23,244	14,388	9,930	4,535	7,293

The number of mines that contributed to total production in 1951 was three times that in 1950. Of the 47 properties that produced some metal during the year, however, 9 supplied 93 percent of the total. The largest producers were as follows:

California.—Contra Costa County, Mount Diablo mine; San Benito County, Juniper and New Idria (including San Carlos); Santa Clara County, New Almaden dumps; Sonoma County, Culver-Baer and Mount Jackson (including Great Eastern) mines.

Idaho.—Valley County, Hermes mine.

Nevada.—Humboldt County, Cordero mine.

Oregon.—Douglas County, Bonanza mine.

Of this group the Mount Diablo, Hermes, and Bonanza mines did not operate in 1950; the Mount Diablo did not begin to produce until the final quarter of 1951. All of the large contributors in 1951 had produced substantial quantities of mercury in the past.

In 1950, 11 mines supplied 99 percent of the United States total; in 1949, 7 mines produced 98 percent, but in 1942 it took 34 mines to furnish 89 percent.

1939	191,892	18,505	7.3				

[1] Excludes mercury produced from placer operations and from clean-up activity at furnaces and other plants.

The long-time downtrend in grade of mercury ore treated in the United States was interrupted in 1944–47 but subsequently has been resumed; in 1951 the average grade was 2.8 pounds per ton lower than in 1950, 3.8 pounds under 1949, and 6 pounds under 1947.

In addition to the mercury produced at the mines in 1951, at least 2,000 flasks (the same as in 1950) was reported produced from old battery plates and other scrap compared with 1,385 flasks in 1949. Additional unreported quantities doubtless were recovered.

REVIEW BY STATES

Arizona.—A few flasks of mercury were reported to have been purchased from a property on Slate Creek adjoining the Ord mine. This is the first production reported since 1946.

California.—Production in California increased 11 percent in 1951, and the State retained its rank as the leading mercury-producing area in the United States; it contributed, however, only 59 percent of the total compared with 85 percent in 1950 and 69 to 45 percent in 1945 to 1949, inclusive. The Mount Jackson (including Great Eastern) mine, Sonoma County, continued to be the largest producer, not only in California but in the United States as well. Production came from 26 other properties, a total of 27 compared with 14 in 1950; 7 of the foregoing properties reported production from clean-up, dump, or placer operations. Ten counties—Contra Costa, Del Norte, Fresno, Lake, Napa, San Benito, San Luis Obispo, Santa Clara, Sonoma, and Yolo—reported production in 1951.

Mercury produced in Contra Costa County came from the Mount Diablo mine, where a rotary furnace was used.

All production in Del Norte County was from the Patricks Creek (Webb) mine, where more than one operator was active during the year.

At the Archer mine in Fresno County the 80-ton Gould furnace was operated intermittently for 4 months; 72 flasks of mercury were produced.

Digitized by Google

The Sulphur Bank, Abbott and Mirabel mines made the small output reported in Lake County.

Mercury was produced from old mine dumps at the James Creek and Knoxville mines, and some was recovered from sand and gravel washed down from dumps at the Oat Hill, all in Napa County.

In San Benito County nine properties contributed to the county total of 971 flasks. The New Idria mine—leading producer in the United States during World War II and second only to New Almaden, Santa Clara County, in total output from the start of production in this country over 100 years ago—resumed mining operations in the third quarter of 1951 and was the fourth-largest producer for the year as a whole. The property had been idle, except for clean-up activity, since 1948. In all, 7,671 tons of ore was mined and furnaced in 1951 and produced 643 flasks of metal; an additional 60 flasks resulted from treating dump material. The operator concentrated on reopening and repairing the mine, which had caved badly during the shut-down period. Extensive repairs to plant and surface equipment were also necessary. The mine is equipped with four 5- by 56-foot rotary furnaces. Some of the ore produced at the Juniper mine and the entire North Star tonnage was treated in New Idria's plants. Other productive properties in the county were the Valley View (Panoche), which had more than one operator, the Lone Oak, and Aurora (at all of which retorts were in use), and three others.

In San Luis Obispo County a small quantity of mercury was produced from a test run at the Rinconada mine.

Mercury was produced by several licensees at the New Almaden property as well as at the Guadalupe mine, both in Santa Clara County. All output at New Almaden ceased when the property was leased to the Cordero Mining Co. late in the year. The company obtained a Defense Minerals Exploration Administration contract to explore the property.

The Mount Jackson (including Great Eastern) mine, Sonoma County, was one of only three large mines in operation throughout the year. The Culver-Baer and Dewey-Buckman (formerly Dewey-Geyser) mines also produced in 1951; both used rotary furnaces. At the Culver-Baer, production in 1951 substantially exceeded that in 1950. Production at Dewey-Buckman was incidental to the main activity of developing ore, moving the furnace from the Contact mine, and other preparatory work. V. C. Harrison produced mercury in a retort at the Ella B. Eureka property.

A small quantity of mercury was recovered at the Reed mine, Yolo County.

Idaho.—The Hermes mine, Valley County, inactive since July 1948, resumed output in 1951 and was the only producer in the State. In all, 357 flasks were produced from 3,200 tons of ore treated in one of the two 80-ton rotary furnaces at the mine. As in 1948, the mine ranked fifth in the United States.

Nevada.—Nevada ranked second to California in output of mercury in 1951, a position held also in 1950 and 1949. The Cordero mine, Humboldt County, resumed production in the latter part of the year; it was the second-largest producer in the United States for the year as a whole, as it was in 1950, when production likewise was

Digitized by Google

restricted to less than a 6-month period. Other counties that produced some mercury in 1951 were Esmeralda, Nye, and Pershing. Twelve properties were productive.

In Humboldt County, in addition to the Cordero, the Cahill, Grayson Group, and Turillas mines also reported production. At the Cahill 29 flasks were recovered from 162 tons of ore treated in a rotary furnace. The operator was driving under existing workings in an effort to cut favorable structures at depth. Ore was retorted at the Grayson and dump material at the Turillas.

Elsewhere in the State production came from small retort operations at the Red Rock, in Esmeralda County; the Quicksilver Stone No. 1, Nevada Cinnabar, A & B, and Mercury Mine, in Nye County; and Hillside and one other, in Pershing County. One productive small mine, also in Pershing County, is equipped with a furnace.

Oregon.—Production of mercury resumed importance in 1951 with reopening in March of the Bonanza mine, Douglas County, closed since November 1949. At the mine, from which came all but a very small part of the total for the State, 12,180 tons of ore were mined and treated in a 4- by 6-foot rotary furnace, yielding 1,160 flasks of mercury. A 14-foot Herreshoff furnace at the mine was not operated. The Bonanza was the third-largest producer in the United States in 1951. Extensive development work was reported being carried on at both south and north extremities of the Bonanza vein. Most of the production in 1951 came from the 370 and 500 levels of the mine along the south ore zone, which had been bypassed for many years.

The Bonanza-Nonpareil district was described.[1]

Small quantities of mercury were produced in Oregon also at the Maury Mountain mine, Crook County; at the newly discovered property known as Deer Creek, in Grant County; and from cleaning-up operations at the Black Butte mine, Lane County.

According to a report describing the mercury deposits of the Horse Heaven district, cinnabar was discovered in commercial quantities in this district (north-central Oregon) in 1933, and the district has produced 15,000 flasks since then. The report states that most of the metal came from the Horse Heaven mine but that the Axe Handle has produced about 150 flasks.[2] The district was idle in 1951.

Texas.—Mercury was produced in Texas in 1951 for the first time since 1945. Two properties in Brewster County made the small production, the major part of which was from cleaning-up operations at a Scott furnace.

CONSUMPTION AND USES

The record peacetime consumption in 1951 resulted chiefly from the putting into operation of a new chlorine and caustic-soda plant late in the year. Such use of metal is not dissipative, although some mercury is lost in operating the plant. Were demand for chlorine and caustic soda to decline markedly or very urgent demands for mercury develop, the metal in chlorine plants and in such other plants as

TABLE 5.—Mercury consumed in the United States, 1947–51, in flasks of 76 pounds

Use	1947	1948	1949	1950	1951
Pharmaceuticals	3,047	3,382	3,443	5,996	2,761
Dental preparations	[1] 785	[1] 994	[1] 963	[1] 1,458	[1] 803
Fulminate for munitions and blasting caps	523	441	149	289	494
Agriculture	5,617	7,048	4,667	4,504	7,737
Antifouling paint	760	996	1,683	3,133	2,500
Electrolytic preparation of chlorine and caustic soda	693	806	755	1,309	1,543
Catalysts	5,078	3,262	2,520	2,743	2,635
Electrical apparatus	[1] 6,763	[1] 6,471	[1] 7,323	[1] 12,049	[1] 10,250
Industrial and control instruments	[1] 5,394	[1] 5,653	[1] 5,016	[1] 5,385	[1] 6,158
Amalgamation	138	143	165	192	154
General laboratory	333	442	345	646	524
Redistilled	[1] 4,689	[1] 6,499	[1] 6,642	[1] 7,600	[1] 8,776
Other	1,761	10,116	6,186	3,911	12,513
Total	35,581	46,253	39,857	49,215	56,848

[1] A partial breakdown of the "redistilled" classification showed 48 percent was for instruments, 9 percent for dental preparations, and 34 percent for electrical apparatus in 1951, compared with a range of 53 to 51, 16 to 10, and 22 to 16, respectively, in the 4-year period 1947–50.

mercury-boiler installations could be reclaimed and reused. If and when such plants are dismantled the metal reclaimed and used for other purposes is not included in Bureau of Mines statistics as consumption.

Consumption of mercury for agricultural purposes made a noteworthy increase to 7,737 flasks—72 percent above 1950. The manufacture of industrial and control instruments took 14 percent more than in 1950. Both uses consumed more mercury than in any other year in the period 1939 to date covered by detailed consumption data.

TABLE 6.—Mercury consumed in the United States, 1944–45, by months, and 1946–51, by quarters, in flasks of 76 pounds

Month	1944	1945	1946	1947	1948	1949	1950	1951
January	3,400	5,200						
February	3,700	5,100	6,800	9,000	10,000	10,400	10,600	16,000
March	3,600	6,100						
April	3,200	7,500						
May	3,100	8,900	8,100	8,500	15,700	7,600	11,300	11,600
June	3,400	8,500						
July	3,000	6,600						
August	3,900	5,300	7,400	7,700	9,400	8,000	12,400	7,400
September	3,900	3,100						
October	3,900	3,100						
November	3,900	2,500	8,900	9,900	10,300	13,900	15,300	21,600
December	3,900	2,000						
Total: Preliminary	42,900	63,900	31,200	35,100	45,400	39,900	49,600	56,600
Final		62,429	31,552	35,581	46,253	39,857	49,215	56,848

Most mercury uses took less metal in 1951 than in 1950; pharmaceuticals and dental preparations showed drops of 54 and 45 percent, respectively; electrical apparatus consumed 15 percent less mercury than in 1950.

Four new chlorine and caustic-soda plants using mercury cells were planned to go into operation in the near future. These are at McIntosh and Muscle Shoals, Ala.; Calvert City, Ky.; and Plymouth, N. C. In addition, some currently operating plants were being enlarged.

An extensive program for relighting 334 miles of the 1,350 miles of improved streets in Seattle, Wash., was about one-third completed by

Digitized by Google

August 1, 1951. Mercury lamps were selected because it was claimed that fewer units per block gave equal illumination with lower power consumption.[3]

Other articles that appeared during the year discussed improvements in mercury lamps, properties of various types of lamps, and other lighting factors.[4] Current operating results and developments at mercury boiler power plants were also described,[5] as were measures taken to assure protection from mercury leakage at mercury power plants.[6] Articles were also published on the use of sensitized paper for estimation of mercury vapor[7] and on some of the general hazards involved in using mercury and precautions required in its handling and use.[8]

An article published during the year described a new magnetic mercury cathode designed for use in making quantitative analytical separations. It was said to be particularly useful where large quantities of interfering metals must be separated from small quantities of other elements to be assayed.[9] Another article described the mercury cathode polarographic method of determining titanium in rocks.[10]

STOCKS

Above-normal industry stocks of 35,619 flasks at the beginning of 1951 were reduced to 30,172 flasks by the end of the year, an anticipated drop, owing chiefly to withdrawal of metal held for a large chlorine-plant installation. The inventories continued to be greater

TABLE 7.—Stocks of mercury in hands of producers and of consumers and dealers, 1947–51, in flasks of 76 pounds

End of year	Producers	Consumers and dealers	Total
1947	3,084	16,200	19,284
1948	5,165	25,000	30,165
1949	5,354	15,600	20,954
1950	2,719	32,900	35,619
1951	1,072	29,100	30,172

than customary, however, because before the year ended metal was being accumulated for further new installations to come into operation in 1952 or later.

Of the total metal stocked, the small part held by producers was reduced 61 percent in 1951, continuing the decline since 1949. The holders of much of the 1949 quantity, unwilling to dispose of their metal at less than the cost of production, were rewarded for their patience and were able to sell at much higher prices than could have been obtained from the end of World War II to 1951.

In addition to the metal shown in table 7, noteworthy quantities of mercury are held in the National Stockpile, but data on such quantities may not be disclosed.

PRICES

A sharp uptrend in prices was in progress at the beginning of the year, when the range in quotations was $150 to $153 a flask. The upward movement continued until the range reached $225–$227 for the week ended January 24. The upsurge in prices following the outbreak of hostilities in Korea—June 1950—thus followed the pattern established at the outset of World War II in 1939. In 7 months after the Korean disturbance, however, prices virtually trebled, whereas in the earlier period, of similar length, prices little more than doubled. Both movements were spectacular. Government price-control action, described below, prevented prices from rising further. They generally tended to decline from the last week in January until the latter part of August, when the price range was $195–$200. After August the price moved upward to an average of $216.96 in October, following which another decline began. The year's closing quotations were $212–$215 a flask.

The General Ceiling Price Regulation, issued by the Economic Stabilization Agency on January 26, provided that prices of mercury, among many other commodities, be held at not to exceed the highest prevailing from December 19, 1950, to January 25, 1951, inclusive.

TABLE 8.—Average monthly prices per flask (76 pounds) of mercury at New York and London, and excess of New York price over London price, 1949–51

Month	1949			1950			1951		
	New York [1]	London [2]	Excess of New York over London	New York [1]	London [2]	Excess of New York over London	New York [1]	London [2]	Excess of New York over London

The regulation established ceilings on an individual company basis; and most producers were caught without a ceiling price, not having made sales during the specified period. The problem thus created could be solved only by the Office of Price Stabilization setting individual ceilings. Mercury was exempted from price control by General Overriding Regulation 9, Amendment 4, which likewise dropped some other strategic items from price control.

In London mercury was quoted at £48 (equivalent to $134.40 a flask) per long ton during the first week in January, rose to £73 10s. (equivalent to $204.54 a flask) in the last week in the month, and remained there until the latter part of March, when it rose to £73 15s. (equivalent to $204.61) where it continued for the remainder of the year.

FOREIGN TRADE [11]

Imports of mercury into the United States dropped 15 percent from 1950 and 54 percent from 1949 but were higher, nonetheless, than in all other peacetime years; the quantity for 1951 was 30 percent less than in the war year 1945. The all-time peak in 1949 was due largely to purchases by the ECA with counterpart funds for the National Stockpile, a factor that did not influence entries in 1951.

[11] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Digitized by Google

Anticipated defense requirements and speculation caused the large receipts in 1950. The noteworthy expansion in demand for chlorine for defense purposes was a factor in the maintenance of large imports of metal in 1951.

Exports of mercury declined 46 percent in 1951, continuing the downtrend in progress since 1945 in this regularly small quantity item. Exports were equivalent to less than 1 percent of imports in 1951. Reexports, also regularly small, dropped 24 percent—a continuation of the decrease since 1947.

Imports.—Of the 47,860 flasks of mercury imported for consumption in 1951 (1950 in parentheses), 21,868 (14,973) came from Italy, 11,854 (28,462) from Spain, 6,459 (5,529) from Yugoslavia, 5,109 (3,480) from Mexico, and 2,570 (3,636) from other countries.

General imports—a better measure of goods actually arriving in the country during a given period—were 44,925 flasks in 1951 (60,564 in 1950). Of the 1951 total, 17,633 (18,073 in 1950) flasks came from Italy, 13,608 (29,439) from Spain, 6,523 (5,980) from Yugoslavia, 4,988 (3,986) from Mexico, 660 (107) from Canada, 250 (793) from Japan, and the remainder from countries that normally import mercury.

Imports of mercury compounds, generally insignificant, more than tripled those in 1950 and were the largest since 1937. Receipts of mercuric chloride in 1951 were 22,598 pounds from Yugoslavia, 2,205 pounds from Spain, and 112 pounds from the United Kingdom; of oxide (red precipitate), 3,307 pounds from Germany and 1,400 pounds from the United Kingdom; and of mercury preparations not specifically provided for, 53,286 pounds, of which 48,590 pounds were from Sweden, 4,480 from Italy, 110 from Belgium, and 106 from Yugoslavia.

Exports.—Of the exports of 241 flasks, 55 (43 in 1950) went to Venezuela, 40 (215) to Canada, 22 (70) to Colombia, 20 (15) to Cuba, 18 (none) to Peru, 14 (28) to Brazil, 13 (6) to Belgium and Luxembourg, and smaller quantities to 21 other countries.

TABLE 10.—Mercury exported from the United States, 1946–51

[U. S. Department of Commerce]

Year	Pounds	Flasks of 76 pounds	Value	Year	Pounds	Flasks of 76 pounds	Value

Reexports totaled 675 flasks (886 in 1950). Of the total, 400 (none) went to Japan, 215 (578) to Canada, 37 (221) to Brazil, 17 (46) to Colombia, and the remainder in quantities of 1 or 2 flasks to four other countries.

WORLD REVIEW

World output of mercury rose slightly in 1951 despite a drop of 14 percent in Spain. The Italian rate was virtually unchanged, and that in Yugoslavia continued at the high level attained in 1950. Increases in the United States, Mexico, and China more than offset the decline in Spain and explained the small world gain.

[1] Mercury is also produced in U. S. S. R., but production data are not available; estimates by authors of chapter included in total.
[2] Data not yet available; estimates by authors of chapter included in totals.
[3] Included with Germany.
[4] Revised figure.
[5] Estimate.
[6] Byproduct of pyrites production in Slovakia only.
[7] Includes Austria.
[8] Output of Idria mine (Yugoslavia) included with Italy through 1945.
[9] Less than 1 flask.

Chile.—The quicksilver deposits of Chile were described in a recent cooperative report prepared by members of the Geological Survey, United States Department of the Interior, and the Department de Minas y Petroleo of Chile. The Los Mantos mine, Chile's largest gold mine and the country's only recent producer of mercury, is in the Punitaqui district, Province of Coquimbo.[12]

Italy.—During the year it was estimated that production for 1951 might increase as much as 20 percent over 1950, but no increase developed. Production was from the following companies with mines

[12] McAllister, J. F., Flores W., Hector, and Ruiz F., Carlos, Quicksilver Deposits of Chile: Geol. Survey Bull. 964-E, 1950, 40 pp. (Bull. 964, pp. 361-400).

Digitized by Google

in Tuscany: Societá Monte Amiata, Stabilimento Minerario del Siele, Societá Mineraria Argus, and Societá Italiana An. Mercurio (S. I. A. M.). Monte Amiata was said to have accounted for 50 percent of the 1950 production and Stabilimento Minerario del Siele about 25 to 30 percent. Monte Amiata was engaged in a 800,000,000-lire program for rehabilitation and expansion of output. The program was aimed at mechanization of mine and furnaces. The company was rehabilitating and mechanizing its mine at Morone (Siena). This mine, closed for more than 20 years, was scheduled for full production in October or November 1952. Stabilimento Minerario del Siele also was undertaking a program of modernization and of expansion of output. Italian consumption of mercury was said to be 8,000 to 10,000 flasks annually.[13]

Mexico.—The increased production—from 3,713 flasks in 1950 to 8,093 flasks in 1951—caused Mexico to replace the United States as the fifth largest producer in the world. Output of the U. S. S. R. is not known, but doubtless it easily outranked that of Mexico and the United States in both years.

Peru.—Mercury mines in Peru were described in a report published in 1951. The report points out that the Huancavelica district, south-central Peru, was the world's largest quicksilver-producing area for over a century and a half. During the Spanish colonial period, it states, the mines produced over 1,400,000 flasks, most of which came from the Santa Barbara mine. Little has been produced in the past 100 years, and it appears unlikely that the district will again become an important quicksilver-mining center unless new discoveries are made.[14]

Spain.—New equipment ordered from the United States is expected to increase the production capacity of the Almaden mine materially.[15] An early estimate placed production in 1951 at 75,500 flasks, but a later report indicated this total was grossly overstated and cut the quantity to 44,480 flasks. The all-time record output of 86,473 flasks was established in 1941. Domestic consumption in 1951 was about 3,000 flasks and exports 48,310. The United Kingdom took 32 percent of total exports, the United States 20 percent, France 13 percent, Switzerland 11 percent, and Germany 9 percent. Until the end of the year export sales were limited to small quantities to avoid speculation.[16]

United Kingdom.—In the post-World War II period the United Kingdom has ranked second only to the United States in consumption of mercury. The sharp reduction in imports of mercury in 1951 was not unexpected, in view of the receipt of excessive quantities in 1950. Entries in 1950 were three times imports in 1949 and one and one-half times the prewar average for 1935–38. Imports were 18,780 flasks in 1951 and 54,199 in 1950 and reexports 6,127 and 14,317 flasks, respectively, leaving 12,653 and 39,882 flasks of newly imported metal available for consumption in the 2 years. These figures do not consider inventories of mercury, which are not reported.

Mica

By Waldemar F. Dietrich, Robert D. Thomson, and G. E. Tucker

GENERAL SUMMARY

DOMESTIC production of sheet mica during 1951 remained small in terms of world production, but the United States continued to be the principal producer of ground mica. Sheet-mica output in 1951 increased 3 percent in quantity and 27 percent in value. The quantity of scrap mica and mica recovered from kaolin and schist sold or used by the producers increased 4 percent. Consumption of mica splittings increased 24 percent; production of built-up mica, which is made from splittings, increased 18 percent.

A report on the occurrence, geographical distribution, mining, and marketing of mica in the United States was published during 1951 by the Bureau of Mines.[1] The U. S. Geological Survey published a report on the physical characteristics of commercial sheet muscovite mica in the southeastern United States. Over 230,000 pieces of mica from at least 850 deposits in Alabama, Georgia, North Carolina, South Carolina, and Virginia were tested for this report.[2] Summaries of pegmatite investigations in Colorado, Wyoming, Utah, Idaho, and Montana were recently released by the U. S. Geological Survey.[3]

TABLE 1.—Salient statistics of the mica industry in the United States, 1947–51

	1947	1948	1949	1950	1951

DOMESTIC PRODUCTION

Sheet Mica.—Production of sheet mica in 1951 increased slightly to 595,000 pounds valued at $160,000, representing a minor percentage of total sheet-mica consumption. Uncut punch and circle mica in 1951 represented 92 percent of the total sheet output. Of the 5 States reporting production, North Carolina ranked first with 78 percent of the total domestic production.

Mica is produced in the United States by a large number of small producers, many of which are not canvassed by the Bureau of Mines. Statistics for sheet-mica production must be compiled from reports submitted by purchasers. High cost of production restricts extensive production in the United States. Domestic production cannot compete with mica produced from deposits of equivalent mica content in certain foreign countries having low-cost labor because of large hand-labor requirements to mine, process, and prepare sheet mica. However, a shortage of good-quality sheet mica in 1951 enlivened the interest in domestic production, actual and potential. Exploration of domestic pegmatites in search of sheet mica and other strategic minerals was assisted by provisions of the Defense Production Act of 1950. Numerous exploration loans were made available to mica miners.

During the year, the W. N. C. Miners' Association was founded by the miners of Franklin, N. C., to include all miners and producers of mineral ores in the tri-State area (North Carolina, Georgia, and Tennessee). Main objectives of the association were to assist fulfillment of national defense requirements for mica and other minerals and gain closer relationships between industry and Government.

Scrap Mica.—Sales of scrap mica, including reclaimed mica, to grinders in 1951 totaled 71,900 short tons, an all time high for this industry. Of the total, scrap mica amounted to 59,500 short tons valued at $1,475,000 and reclaimed mica, recovered from kaolin and mica schist, totaled 12,400 short tons valued at $409,000.

TABLE 3.—Scrap and reclaimed mica sold or used by producers in the United States, 1935–39 (average) and 1947–51

[2] Figure withheld to avoid disclosure of individual company operations.

Ground Mica.—Sales of ground mica totaled 70,100 short tons valued at $3,843,000, a decline of 3 percent and 2 percent, respectively, compared to 1950. Dry-ground mica represented 84 percent of the total sales. Producers were vigorously searching for new and expanded markets.

CONSUMPTION

Sheet Mica.—In 1951, apparent consumption of sheet mica, which comprises block, film, and splittings, totaled 17.5 million pounds, representing about a 20-percent increase over the previous year (table 5). About 97 percent of the consumption was supplied from foreign sources. Block and film mica were used mainly in the manufacture of electrical commutators; armatures; radio, television, and radar tubes; capacitors; and household appliances, such as flatirons and toasters.

Digitized by Google

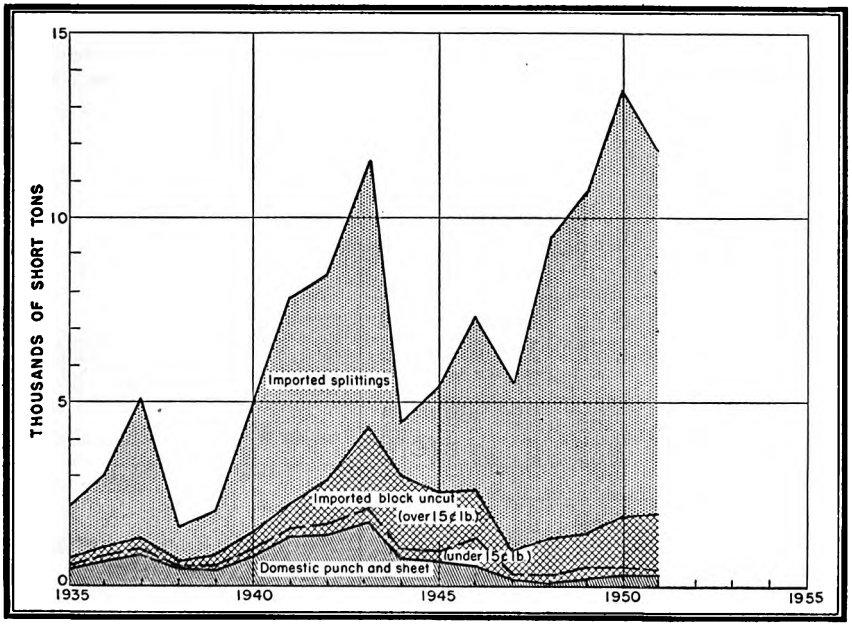

FIGURE 2.—Block mica and splittings imported for consumption in the United States and sales of domestic sheet and punch mica, 1935–51.

Considerable difficulty continued to be experienced in acquiring adequate quantities of both block and condenser film for the National Stockpile.

Consumption of mica splittings, as reported by consumers, reached an alltime high of 13.4 million pounds valued at $11.8 million (table 6). Approximately 92 percent of the splittings supply was imported from India. Consumer stocks were near a normal and adequate level. Supplies of Indian muscovite splittings and Madagascan phlogopite splittings were adequate for industry's needs and National Stockpile requirements. Stockpile goals for splittings were reached during the year.

TABLE 5.—Production of sheet and punch mica and apparent consumption of sheet and punch mica and mica splittings in the United States, 1942–51, in pounds

Year	Production	Apparent consumption	Year	Production	Apparen consumption
1942	2,761,844	12,888,273	1947	415,589	11,302,644

Built-up mica.—The production of 9.5 million pounds of built-up mica (made from splittings) valued at $26.3 million in 1951 was the greatest output recorded in a single year. Manufacture of segment plate used 29 percent of the total quantity of built-up mica; molding plate, 23 percent; and all other (tape, etc.) 26 percent.

TABLE 7.—Built-up mica[1] sold or used in the United States, 1949–51, by kind of product

Product	1949		1950		1951	
	Pounds	Value	Pounds	Value	Pounds	Value

[1] Made from splittings.

Ground Mica.—Ground mica sold or used by producers in 1951 totaled 70,100 tons. This was a slight decrease in comparison to the 72,300 short tons consumed in 1950.

Approximately 40 percent of the ground mica was used by the roofing industry. The remainder was consumed by a large number of other industries of which paint industry used 17 percent; rubber industry, 9 percent; plastics industry, 2 percent; and wallpaper industry, 1 percent.

TABLE 8.—Ground mica (including mica from kaolin and schist) sold by producers in the United States to various industries, 1950–51

Industry	1950			1951		
	Short tons	Percent of total	Value	Short tons	Percent of total	Value

PRICES

Prices of domestic sheet mica increased during the year but were not high enough to permit domestic producers in most instances to compete with low-cost output from foreign sources. Quoted prices for domestic mica are nominal, and actual selling prices are generally determined by direct negotiation between buyer and seller under agreement as to grade and quality of particular lots. The following quotations from E&MJ Metal & Mineral Markets serve only as a general indication of the range of prices during 1951: North Carolina district, clear sheet, 1½ by 2 inches, 80 to 85 cents per pound; 2 by 2 inches, $1.10 to $1.20; 2 by 3 inches, $1.50 to $1.60; 3 by 3 inches, $1.80 to $1.90; 3 by 4 inches, $2.20 to $2.30; 3 by 5 inches, $2.40 to $2.50; 4 by 6 inches, $2.15 to $3.25; 6 by 8 inches, $4.00 to $4.50; and punch mica, 12 to 22 cents per pound, according to size and quality. Stained or electric mica was sold at approximately the same prices as clear sheet.

North Carolina wet-ground mica ranged from $140 to $155 per ton during 1951, depending on fineness and quality; dry-ground from $32.50 to $70; and scrap, $32 to $35, depending on quality.

Raw mica and mica parts, except mica scrap and ground mica, wet and dry, were decontrolled by GOR–9, May 1, 1951.

FOREIGN TRADE [5]

Imports.—In 1951, imports of mica of all types totaled 18,889 short tons, compared with 18,511 (revised) in 1950. Mica, not cut or stamped to dimensions, not above 12/10,000 of an inch in thickness, represents the bulk of the splittings for built-up mica. Imported splittings in 1951 totaled 19.1 million pounds, as compared to 23.1 million pounds in 1950. Approximately 93 percent of the total splittings imports came from India. The remaining 7 percent came mainly from Madagascar and Canada and was phlogopite splittings. Imports of unmanufactured mica valued above 15 cents per pound, plus the imports from Brazil of manufactured films and splittings, not cut or stamped to dimensions, over 12/10,000 inch in thickness, is an approximate index of the imports of block mica suitable for electronic applications. In 1951 these items totaled 3,796,000. The imports from India over 12/10,000 of an inch thick, generally accepted as film, amounted to 1,050,000 pounds during the year.

Exports.—Total exports of mica and mica products in 1951 increased 22 percent in quantity and 28 percent in value over 1950. Exports of unmanufactured mica to Canada represented 73 percent of the total unmanufactured exports, and Belgium-Luxembourg 15 percent. Exports of manufactured mica, excluding ground or pulverized, to Canada represented 61 percent of such exports, Mexico 10 percent, and Austria 4 percent.

[5] Figures on imports and exports compiled by M. B. Price and E. D. Page of the Bureau of Mines, from records of the U. S. Department of Commerce.

[1] Changes in Minerals Yearbook, 1950, p. 796 should read as follows: Unmanufactured (other), valued above 15 cents per pound—Brazil, 1,213,144 pounds ($1,031,958) and India, 955,494 pounds ($1,552,265).
[2] Revised figure.

TECHNOLOGY

Research at the Bureau of Mines Electrotechnical Laboratory, Norris, Tenn., continued on synthesis of mica, and some progress was reported. Sheets of mica with physical characteristics comparable with natural mica have been produced but only in small sizes. A general history of the progress in synthetic mica was published recently.[6] The Office of Naval Research, Department of the Navy, issued a report on Samica mica paper, describing the Samica process and possible uses of the new mica-paper insulator.[7] Experiments on a new method for recovering flake mica were reported.[8] English Mica Co., Spruce Pine, N. C., has installed Humphrey spirals to aid recovery of mica.[9]

Recently, a patent was issued for producing an electrical coating on glass and mica.[10] Mica Insulator Co. issued a publication discussing properties, applications, facilities, and services of micanite and additional information pertaining to laminated plastics, varnished fabrics, and specialty coatings.[11] Two firms were reported to be planning commercial production of sheet mica from domestic scrap mica as a possible substitute for built-up mica products made from imported splittings.

WORLD REVIEW

Angola.—Production of mica increased to 136 metric tons in 1951 from 24 tons in 1950. The principal producing vein was reported nearly exhausted at the end of the year. At the only other mine of importance, production improved slightly in quantity and quality, although classification standards remained low.[12]

Argentina.—The Argentine Government established a price control on mica properly graded and packed in export containers delivered at the warehouse. Prices for stained mica ranged from 1.40 pesos per kilogram ($0.13 per pound) for punch to 170 pesos per kilogram ($15.45 per pound) for AA grade.

Brazil.—The U. S. Geological Survey recently released a publication on the geologic relations of pegmatites, production statistics and other information relative to mica in Minas Gerais, Brazil.[13]

Canada.—Sales of mica totaled 1,328 metric tons in 1951, a decline from the 1,760 tons reported in 1950. The Purdy mica mine at Eau Claire, Ontario, an outstanding producer of muscovite during World War II but closed in 1945, was reopened in 1951.[14] General geology, occurrence, and origin of mica in southeastern Ontario was discussed in an article.[15]

India.—A book of great interest and practical value covering all aspects of the India mica industry was published during 1951. Discussions of the geology, methods of prospecting, mining, and marketing mica are contained in this book.[16] An abstract of an article on Mica Industry of India—Its History and Development was published by the Bureau of Mines.[17]

The Mica Advisory Committee met in December 1951, at Jaipur, Rajasthan, to consider a number of proposals. One of them was that licenses for mica mining in Rajasthan be restricted to check overproduction of mica. The committee decided to recommend that export of scrap mica be banned for a year and advised the Railway Board to consider the use of funds collected under the Mica Mines Labor Welfare Act 1946 for road construction in the mica-mining areas. Fixing of mica prices was not proposed since the committee was of the opinion that there was no danger of the fall in prices in the United States adversely affecting the Indian mica industry.[18]

[1] In addition to countries listed, mica is also produced in China, Colombia, Ethiopia, Rumania, and U. S. S. R., but data on production are not available; estimates for these countries are included in total.
[2] Revised figure.
[3] Imports into United States.
[4] Data not available; estimate by senior author of chapter included in total.
[5] Exports.
[6] Less than 0.5 ton.

Madagascar.—Production of phlogopite mica was 958 metric tons in 1951, compared to 819 tons (revised) for 1950. The output in 1951 consisted of 70 metric tons of block mica and 888 tons of splittings. About 90 metric tons of block mica and 593 tons of splittings together valued at 169,236,028 francs were exported, of which the United States received 87,783,406 francs worth.[19]

The ECA purchased 150 metric tons of phlogopite mica in 1951 from Syndicat du Mica de Madagascar.[20] This was the first Marshall Plan purchase of Madagascan mica.

As of January 18, 1951, the export tax on mica was reduced from 7 percent to 5 percent ad valorem.[21]

Molybdenum

By Robert W. Geehan

GENERAL SUMMARY

MOLYBDENUM and many other alloying metals were in short supply in 1951, and industry and the Government took steps to increase production and eliminate nonessential uses. The metal was employed in certain alloys to replace other ferroalloy metals that were even scarcer; this was particularly true of tool steel, where molybdenum replaced tungsten. During the early part of the year exports of molybdenum concentrates were at a very low level, but foreign trade was resumed at a more normal rate in the second half of 1951. Shipments for export of molybdic oxide, calcium molybdate, ferromolybdenum, and other primary products decreased 29 percent in 1951; production, on the other hand, increased 29 percent. Because of the increased demand for molybdenum concentrates in 1951, the quantity of concentrates converted to oxide was 29 percent more than in 1950. The output of concentrates increased in each quarter-year period from the last quarter of 1949 through the second quarter of 1951; however, during the third and fourth quarters of 1951 there was a slight decrease.

Production and shipments of molybdenum concentrates were 36 percent more and 15 percent less, respectively, in 1951 than in 1950. Colorado advanced from second to first place as a molybdenum-producing State and replaced Utah, which dropped to second place.

Industry stocks of molybdenum concentrates were 17 percent higher at the end of 1951 than at the close of 1950, and stocks of molybdenum products held by producers were 103 percent more.

There was no change in the quoted price of molybdenum concentrates in 1951.

TABLE 1.—Salient statistics of molybdenum concentrates in the United States, 1947–51

	Molybdenum contained, thousands of pounds				
	1947	1948	1949	1950	1951
Production	27,047	26,706	22,530	28,480	38,855
Shipments (including exports)	22,190	29,669	23,280	44,544	37,955

GOVERNMENT REGULATIONS

To stimulate the production of molybdenum the Government entered a long-term contract with Climax Molybdenum Co. in 1950; this contract was modified in 1951 to call for still greater output. Certificates of necessity covering a portion of the cost of new facilities were issued. Negotiations with copper producers for expanded production were initiated, and an increase in output of byproduct molybdenum was expected to result; similar negotiations with potential producers of molybdenum took place to lead to a further increase in direct production.

Several orders, designed to conserve the metal and provide for control of its distribution, were issued and are listed below:

National Production Authority orders:

M–33. Allowable inventory.
M–52. Reduced the percentage of molybdenum content which could be used in certain stainless steels.
M–1. Amended April 6. Established procedure for virtually complete control over the use of ferro-alloys in the production of alloy iron, steel, or nonferrous products.
M–80. Modification of above regulations.
M–81. Established procedure for control of substantially pure tungsten and molybdenum.
M–30. This order applied to tungsten but led to the use of increased amounts of molybdenum in tool steel.

Defense Minerals Administration orders (later Defense Materials Procurement Agency orders):

MO–8. Allocation of molybdenum ore and concentrates.

Office of Price Stabilization.

The general ceiling price regulation governed molybdenum concentrates and primary products.

The International Materials Conference Committee on Molybdenum and Tungsten issued allotments covering distribution of these metals which had been approved by the governments of the member nations. These agreements were in force during the third and fourth quarters of 1951. The molybdenum allotment for the third quarter was as follows, in metric tons of metal: United States 3,420, United Kingdom 515, France 195, Germany 125, Sweden 100, reserve 45. It was agreed that "normal" shipments, for export, of primary products would be continued by these nations. The distribution for the fourth quarter was as follows, in metric tons of metal: United States 3,620, United Kingdom 538, France 232, Germany 157, Sweden 106, Japan 40, Italy 20, Netherlands 5, and reserve 2. These quantities included specific allowances for metal to be exported as primary products as follows: United States 90, United Kingdom 25, France 25, Germany 1, and Sweden 13. Later in the quarter a small additional distribution was made to cover a 170-metric ton production that had not been expected; the amounts of distribution and deductions for export of products were: United States 116–3, United Kingdom 17–1, France 7–1, Germany 5–0, Sweden 3–0, Italy 1–0, Japan 1–0, reserve 20.

DOMESTIC PRODUCTION

During 1951 the industry-Government program for expanding production of molybdenum was continued. Production of concentrates totaled 38,855,000 pounds (contained molybdenum), an increase of

Digitized by Google

36 percent over 1950. In addition, development and construction done during 1951 at the Climax deposit were expected to increase productive capacity in future years. A strike at western copper mines temporarily halted production of byproduct molybdenum during the third quarter of 1951.

The chief mineral of molybdenum is molybdenite (MoS_2), which comprised virtually the entire output in 1951; powellite [$Ca(Mo, W)O_4$] contributed a relatively small quantity. The increased use of tungsten concentrates containing an appreciable amount of powellite provided a small amount of molybdenum that does not appear in the statistical tables. Wulfenite ($PbMoO_4$), once mined from several deposits in southwestern United States, has not been produced since 1944.

Molybdenite is produced at mines operated chiefly for molybdenum and as a byproduct of mines operated mainly for copper or tungsten. The molybdenite content of raw ore mined at the former ranges from about 0.4 to 1.5 percent; at the latter the range is about 0.015 to 0.055 percent. In both cases, a molybdenite concentrate is produced; the molybdenite content of the concentrates shipped ranges from about 57 to 94 percent, while 90 percent is considered a standard grade for price quotations.

Molybdenum was produced in six States in 1951; Colorado led, followed in order by Utah, Arizona, New Mexico, Nevada, and California. Output of mines operated solely or almost solely for molybdenum was 22,816,000 pounds in 1951, an increase of 89 percent from 1950 whereas byproduct concentrates from copper and tungsten operations totaled 16,039,000 pounds, a decrease of 2 percent. Byproduct molybdenum represented 41 percent of the total concentrates produced in 1951 compared with 58 percent in 1950.

Shipments of molybdenum concentrates were 37,955,000 pounds (contained molybdenum) in 1951, a decrease of 15 percent from 1950. These shipments comprised 34,685,000 pounds to domestic consumers and 3,270,000 pounds for export.

TABLE 2.—Molybdenum in ore and concentrates produced and shipped from mines in the United States, 1942–51

Year	Production (thousands of pounds)	Shipped from mines		Year	Production (thousands of pounds)	Shipped from mines	
		Weight (thousands pounds) [1]	Value (thousands of dollars) [2]			Weight (thousands of pounds)[1]	Value (thousands of dollars) [2]
1942	56,942	66,437	47,275	1947	27,047	22,190	15,178
1943	61,667	53,955	38,500	1948	26,706	29,669	20,418
1944	38,679	39,423	27,999	1949	22,530	23,280	19,332
1945	30,802	33,683	23,976	1950	28,480	44,544	37,729
1946	18,218	16,787	11,529	1951	38,855	37,955	36,177

[1] Figures for 1942–44 represent shipments from mines, plus concentrates converted to oxide by producer at Miami, Ariz.; those for 1945–51 represent shipments to domestic and foreign customers, plus concentrates converted to oxide at Miami, Ariz., and Langeloth, Pa.
[2] Largely estimated by Bureau of Mines.

Arizona.—The Miami Copper Co. has been a regular producer of molybdenum concentrates since 1938. They are recovered as a byproduct of its copper operations at Miami, Ariz., and are converted

Digitized by Google

to molybdic oxide at the same location. The Phelps Dodge Corp. produced 359 tons of molybdenite concentrates in 1951 as a byproduct of copper mining at its Morenci operations. The Bagdad Copper Corp. began to recover molybdenite concentrates during 1951 and produced 84 tons during the year. Concentrates produced by Phelps Dodge Corp. and Bagdad Copper Corp. are shipped to eastern plants for conversion to products. The S. W. Shattuck Chemical Co. operated the New Year's Eve mine, near Twin Buttes, primarily for molybdenum and produced 31 tons of concentrate in 1951, which was shipped to its Denver, Colo., plant for conversion to oxide and other products. Operations at this mine were discontinued October 31, 1951.

Output from Arizona was 76 percent more than in 1950; as a result, the State advanced from fourth to third place as a producer of molybdenum.

California.—California remained in sixth place as a producer of molybdenum in 1951. The only producer in California was the United States Vanadium Corp. at Bishop, where the metal is recovered as a byproduct of tungsten production. Recovery of molybdenum was 38 percent less than in 1950.

Colorado.—As a result of a 90-percent increase in production, Colorado advanced to first place as a producer of molybdenum in 1951. The Climax Molybdenum Co., operating its world-famous deposit near Climax, Colo., was the only producer of molybdenum concentrates in Colorado during 1951. The following data have been abstracted from the firm's annual report for 1951:

Production in 1951 was 22,538,739 pounds of molybdenum contained in concentrates, contrasted to 11,903,043 pounds in 1950. The mine produced 4,566,548 tons of ore during the year 1951, or substantially at mill capacity. During 1951 approximately 259,000 pounds of tungsten, contained in the form of concentrate, were produced, compared with 162,000 pounds in 1950. In 1951 the byproducts plant for recovery of tungsten, pyrite, tin concentrate, monazite, and topaz was limited to the treatment of residues from about 8,000 tons per day of ore as mined. After February of 1952 the capacity will be 20,000 tons.

An expansion program underway is planned to increase primary mill capacity to 20,000 tons per day. Major elements of facility expansion in addition to the mill include one of the largest gyratory crushers ever built, auxiliary crushing equipment, a 4,700-foot covered conveyor system, additional housing for employees, a reservoir for domestic water supply, a 4-mile 26-inch diameter mill-water pipeline, and the byproducts plant enlargement.

Steps are being taken to expand the broken ore reserve, which was greatly depleted during World War II, to 20,000,000 tons. This quantity of broken ore is needed to maintain an operation at the projected rate of 20,000 tons per day.

The Climax deposit is developed from long adits, and most of the ore is produced by a caving method. However, some ore is produced from an opencut. Slushing practice [1] and automatic traffic controls [2] have been described in articles published in 1951.

Nevada.—In 1951, the Nevada Mines Division of the Kennecott Copper Corp. continued to be the only producer of molybdenite concentrates in Nevada. The concentrates are recovered as a byproduct of the McGill concentrator, where copper ores from the company Ruth and Copper Flat operations and from the Emma Nevada group

[2] Engineering and Mining Journal, Automatic Traffic Controls: Vol. 152, No. 5, May 1951, pp. 94-95.

Digitized by Google

of Consolidated Coppermines Corp. are milled. The output of concentrates was 34 percent less than in 1950.

Small amounts of molybdenum were also recovered from tungsten ore and concentrate produced in Nevada and treated at the Bishop, Calif., plant of U. S. Vanadium Corp. or consumed at steel plants. The former production is included with California, and the latter is not tabulated because of lack of data.

New Mexico.—The Chino Mines Division of the Kennecott Copper Corp., Hurley, and the Molybdenum Corp. of America, Questa, continued to be the only producers of molybdenite in New Mexico in 1951. At Hurley, where molybdenite has been recovered as a byproduct of copper operations since 1937, production in 1951 was 30 percent more than in 1950. The Questa mine, which is operated for molybdenum only, was opened in 1919 and since 1923 has been a regular producer. A portion of the output is now from tailings produced in prior years. Output in 1951 was 24 percent less than in 1950. Concentrates produced at Questa are shipped to the processing plant of the Molybdenum Corp. of America at Washington, Pa., where the company produces ferromolybdenum, calcium molybdate, molybdic oxide, and other molybdenum products.

Utah.—Utah was the second largest molybdenum-producing State in 1951. The only producer is the Utah Copper Division of the Kennecott Copper Corp., which since 1936 has been recovering molybdenite as a byproduct of copper at its Arthur and Magna concentrators. Output of molybdenite concentrates in Utah was 5 percent less in 1951 than in 1950.

Washington.—Kromona Mines, Inc., reported that the Kromona mine, Snohomish County, was under development. A road had been completed to the property. Consolidated Mines & Smelting Co., Ltd., reported that its mine in Ferry County was developing ore. There was no production from Washington in 1951.

CONSUMPTION AND USES

Consumption (as measured by shipments to domestic consumers) of molybdenum products in the United States was 9 percent less in 1951 than in 1950. The defense program and restrictions on nonessential uses distorted the normal use pattern; however, the largest single use for molybdenum continued to be as an alloying element in the manufacture of steels, to which it is added as molybdic oxide, calcium molybdate, or ferromolybdenum. In general, when an entire open-hearth heat is to be alloyed to a degree not exceeding 0.8 percent molybdenum, the addition is in the form of molybdic oxide or calcium molybdate; ferromolybdenum is used when higher percentages of molybdenum are desired. A relatively small quantity of molybdenite is used by a few steel companies as an addition to molten metal in the ladle to raise the sulfur content to improve machinability, in addition to gaining the benefit of the contained molybdenum. Of the total molybdenum used in the United States in 1951, it is estimated that about 66 percent was consumed in steels. Smaller quantities (about 25 percent of the total) of molybdenum, chiefly in the form of ferromolybdenum and molybdic oxide, were employed in gray-iron and malleable castings. Molybdenum is also

Digitized by Google

used in the metallic form in the electrical industry, and alone or in nonferrous alloys for certain high-temperature applications; molybdenum disulfide (molybdenite) is used in special lubricants;[3] and various molybdenum compounds are used as fertilizers, in pigments, in the ceramic industry, and as catalysts.

The most noteworthy changes in the use pattern that resulted from the defense program were increases in use in tool steel, in special high-temperature alloys, and in catalysts and a decrease in the amount used in pigments and in the ceramic industry.

Many references to the possible use of molybdenum as fertilizer are contained in the volume, Bibliography of the Literature on Minor Elements and Their Relation to Plant and Animal Nutrition (4th ed., vol. I, 1948, pp. 724–731, and vol. II, 1951, pp. 90–94), published by Chilean Nitrate Educational Bureau, Inc., 120 Broadway, New York, N. Y. Growth of molybdenum crystals[4] and observations on crystal structure[5] were described in articles published in 1951.

TABLE 3.—Production and shipments of molybdenum products[1] in the United States, 1947–51, in pounds of contained molybdenum

Year	Production	Shipments		
		To domestic consumers	Exports[2]	Total
1947	20,659,700	19,878,500	866,400	20,744,900
1948	24,445,300	23,808,900	1,215,800	25,024,700
1949	19,624,200	15,019,000	1,314,100	16,333,100
1950	25,347,800	32,735,700	1,955,100	34,690,800
1951	32,775,000	29,845,000	1,387,700	31,232,700

[1] Comprises ferromolybdenum, molybdic oxide, and molybdenum salts and metal.
[2] Reported by producers to the Bureau of Mines.

STOCKS

Table 4 shows industry stocks of molybdenum concentrates and products, 1947–51. The industry stocks of both items increased during 1951.

1950	[5] 4,326	1,495	(3)	[4] [5] 5,821
1951	5,058	3,037	(3)	[4] 8,095

[1] At mines and at plants making molybdenum products.
[2] Comprises ferromolybdenum, molybdic oxide, and molybdenum salts and metal.
[3] Figure not available.
[4] Excludes stocks of molybdenum products at consumers' plants.
[5] Revised figure.

PRICES

There was no change in the quoted prices for molybdenum concentrates or primary products during 1951. The published price, f. o. b. mines, of molybdenite in concentrates containing 90 percent MoS_2 was 60 cents a pound (equivalent to $1.00 a pound of contained molybdenum). The prices of the principal molybdenum products are based on 1 pound of contained molybdenum, f. o. b. producer's plant. During 1951 the prices quoted were as follows: Molybdic oxide $1.14, calcium molybdate $1.15, ferromolybdenum $1.32, and molybdenum metal $3.00.

FOREIGN TRADE [6]

Imports of molybdenum in ore and concentrates into the United States are normally small; 8,243 pounds (contained molybdenum) was received in 1951 compared with 2,784 pounds in 1950. Some molybdenum ore and concentrates are occasionally imported for conversion to molybdenum products for export; none has been so imported since 1946.

Exports of molybdenum in concentrates (including roasted concentrates) were 3,729,265 pounds (contained molybdenum) in 1951 compared with 6,234,521 pounds in 1950. Exports were at a very low rate during the first half of 1951 (29 percent of the year's total) but rose to a more normal rate in the last half of the year. United Kingdom and Germany were the chief foreign markets in 1951, taking 47 and 20 percent, respectively.

Exports of ferromolybdenum were 1,483,841 pounds (gross weight)[7] in 1951 compared with 1,178,604 pounds in 1950, and those of molybdenum metal and alloys were 109,129 pounds compared with 146,075 pounds in 1950.

Tariff.—The duty on molybdenum ore and concentrates continued to be 35 cents a pound on the metallic molybdenum contained. The General Agreement on Tariff and Trade, Torquay, effective June 6, 1951, reduced the duty on ferromolybdenum, molybdenum metal and powder, calcium molybdate, and other compounds and alloys of molybdenum to 25 cents a pound of contained molybdenum plus 7.5 percent ad valorem; the former rate was 50 cents and 15 percent ad valorem.

[6] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.
[7] Ferromolybdenum contains about 60–65 percent molybdenum.

Digitized by Google

Austria.—Output of lead-zinc-molybdenum ore in 1950 was 98,631 metric tons compared with 91,016 tons in 1949. The Bleiberg-Kreuth mine in Carinthia is the principal producer. In the first half of 1951, 2,927 tons of lead concentrate, 3,138 tons of zinc concentrate, and 91 tons of molybdenum concentrate were recovered from 53,592 tons of lead-zinc-molybdenum ore.[8]

Canada.—According to the Dominion Bureau of Statistics, 350,000 pounds of MoS_2 was produced by the Molybdenum Corp. of Canada at La Corne, Quebec.

Chile.—Molybdenum is produced as a byproduct of copper mining in Chile. Based on estimated exports, production of molybdenum reached an alltime high of 2,500 metric tons in 1951; production in 1950 was 965 tons (revised).

Norway.—The following is quoted from Mineral Trade Notes.[9]

Most of the molybdenum produced in Norway has been from the Knaben mine near Egersund on the southwestern coast of Norway. Total molybdenum concentrate output from the Knaben mine through 1950 has been about 9,000 metric tons. About 1,000 tons of concentrate has been produced by other mines. Ore from the Knaben mine contains 0.15 to 0.20 percent MoS_2 and is concentrated by flotation to a 95 percent concentrate. Capacity of the plant is about 800 tons of concentrate a year. Mining was suspended in the summer of 1949 in order to concentrate on development work, which had been neglected under German control during the war. The 1950 output was from ore mined in an opencut near the main mine. Before and during World War II a few small molybdenum mines were worked in the Knaben area, in Talemark in southern Norway, at Oterstrand and Laksaadal in northern Norway, and at Sorumsaasen in the Drammen area near Oslo. Norwegian output of molybdenum concentrate has been as follows (in metric tons):

	1938	*1944*	*1949*	*1950*
Knaben	735	387	128	111
Oterstrand	35	18	------	-------
Sorumsaasen	------	7	------	-------
Others	------	1	------	-------
	770	413	128	111

No estimate of ore reserves is known for the Knaben mine. However, possible ore reserves are large, though of low grade. Other molybdenum deposits that have been worked are small.

U. S. S. R.—No information on the magnitude of production has been published; however, an intensive expansion program was known to be in progress in 1947 at the deposit east of Kounrad near Lake Balkhash.

Yugoslavia.—Production is from the Mackatica mine in Serbia. There is no reliable information on 1951 production, but the increased production expected during the year was probably delayed because of lack of machinery.

Natural Gas[1]

By D. S. Colby and B. E. Oppegard

GENERAL SUMMARY

MARKETED production[2] of natural gas in 1950 increased 16 percent to 6,282 billion cubic feet and in 1951 rose another 19 percent to 7,457 billion. Texas, Louisiana, and New Mexico supplied 82 percent of the increase in 1951. Production in Pennsylvania increased after a long static period as the result of discoveries made in 1950.

Consumption of natural gas in the United States in 1951 increased to 7,103 billion cubic feet from 6,026 billion in 1950. North Carolina, South Carolina, Massachusetts, and New Hampshire received natural gas for the first time. Aside from Texas, California and New York

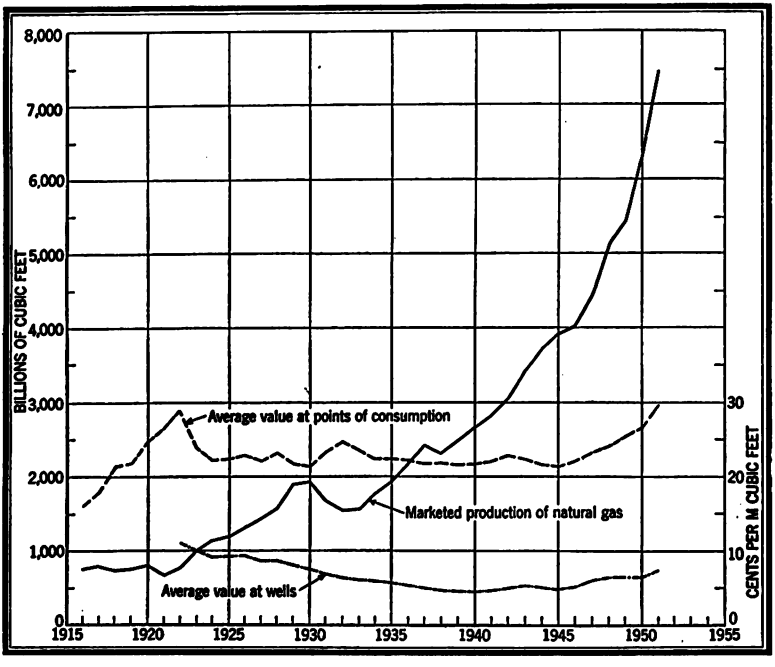

FIGURE 1.—Production and average value of natural gas in the United States, 1916–51.

showed the largest increases in consumption. In each case this increase resulted primarily from completion of an interstate pipeline. The quantities consumed by various classes of consumers in 1951 and the percent change compared with 1950 were as follows: Residential,

[1] Includes final figures for both 1950 and 1951.

[2] Comprises gas either sold or consumed by producers, including losses in transmission, amounts added to storage, and increases in gas in pipelines.

Digitized by Google

1,475 billion cubic feet (+23 percent); commercial, 464 billion (+20 percent); field, 1,442 billion (+21 percent); petroleum refineries, 538 billion (+18 percent); and all other industrial users, 3,184 billion (+14 percent).

The gross quantity of gas placed in underground storage in 1951 was 348 billion cubic feet, more than 50 percent over 1950. The net increase of gas in underground storage during 1951 was 138 billion cubic feet.

The average value of natural gas at the wellhead rose from 6.5 cents per thousand cubic feet in 1950 to 7.3 cents in 1951. This is the sharpest rise in the average value yet recorded during 1 year. Total value of marketed production at the wellhead in 1951 was $543 million. The total value at point of consumption of all natural gas used in the United States in 1951 was $2,119 million, averaging 29.8 cents per thousand cubic feet. This increase of 3.2 cents over the 1950 average was caused in part by a large expansion of consumption in areas removed from the producing fields where gas has a higher value.

Interstate shipments and exports of natural gas increased 27 percent, maintaining the same rate of increase recorded in 1950.

The number of residential consumers of natural gas increased by 4.5 million to 21.4 million. Half of this increase was in the number of consumers of mixed gas, primarily in New York. The number of commercial consumers increased 0.3 million to 1.6 million.

GOVERNMENT REGULATIONS

The United States Supreme Court, in a case involving direct sale of natural gas to an industrial consumer by an interstate gas transmission company,[3] ruled that a State has the right to regulate the sale of natural gas piped across its border if it is to be sold in competition with an established utility.

Secretary of the Interior Oscar L. Chapman on July 27, 1951, approved Bureau of Land Management Circular 1795 requiring all pending and future applicants for natural-gas pipeline rights-of-way

[3] *Panhandle Eastern Pipe Line Co.* v. *Michigan Public Service Commission*, 341 U. S. 329.

Digitized by Google

across public lands to file a stipulation designed to assure the operation of their lines as common carriers, as provided in the Mineral Leasing Act of 1920.

The Petroleum Administration for Defense issued Order 2, effective August 22, 1951, which, with certain specified exceptions, prohibited extension of natural-gas service to new industrial and central heating customers in 15 States and the District of Columbia. The order was deemed necessary because steel shortages prevented pipeline construction from keeping pace with the demand for gas.

On August 22, 1951, the Federal Power Commission issued Opinion 217 on Docket G–1148, a hearing to determine whether Phillips Petroleum Co. was a "natural-gas company" within the meaning of the Natural Gas Act. Phillips does not engage in the interstate distribution of gas but sells at wholesale to interstate pipeline companies. The decision affirmed the position of the Federal Power Commission as recognizing that it had no jurisdiction over transportation or sales made in the process of production or gathering if exercising jurisdiction interfered with the regulatory functions of the States.

As part of an omnibus tax bill passed by the Texas Legislature, a gathering tax of 0.45 cent per thousand cubic feet was levied on natural gas.

RESERVES

Reserves of natural gas, as estimated by the reserves committee of the American Gas Association, were 193,812 billion cubic feet on December 31, 1951, a net increase in reserves of 8.2 trillion cubic feet from the estimate of the previous year. This is the second largest increase reported since estimates were first made by the American Gas Association in 1945. The largest increases in reserves were the addition of 4.3 trillion cubic feet of nonassociated gas in New Mexico and 3.9 trillion cubic feet of dissolved gas in Texas.

PRODUCTION

GROSS WITHDRAWAL

The gross withdrawal of natural gas in the United States increased 12 percent in 1950 to 8,480 billion cubic feet and 14 percent in 1951 to 9,689 billion. There has been a tendency in the last 5 years for production from gas wells to grow relatively more rapidly than that from oil wells. In 1951, 73 percent of the increase in gross withdrawals of natural gas was from gas wells whereas only 67 percent of the gross withdrawals total itself was from gas wells. In 1951 this tendency was most pronounced in New Mexico due to development of the San Juan Basin; however, Kansas, Louisiana, and Texas were among the States following in the same direction.

On the whole, repressuring continued its gradual rise. Oklahoma showed a large increase in 1951 owing to completion of a cycling plant. Texas declined slightly in 1951.

[1] Volumes are reported at a pressure base of 14.65 pounds per square inch absolute and at a standard temperature of 60° F.
[2] Excludes gas loss due to recovery of natural-gas liquids.
[3] The net difference between gas stored in and gas withdrawn from underground storage reservoirs.
[4] Net production equals gross withdrawals less gas injected into underground reservoirs; changes in underground storage are excluded. December production partly estimated.
[5] Includes offshore reserves.
[6] Includes Alabama, Florida, Maryland, Missouri, North Dakota, and Virginia.
[7] Nonassociated gas is free gas not in contact with crude oil in the reservoir.
[8] Associated gas is free gas in contact with crude oil in the reservoir.
[9] Dissolved gas is gas in solution with crude oil in the reservoir.
[10] Gas held in underground reservoirs for storage purposes only.

[1] Marketed production plus quantities used in repressuring, vented and wasted.
[2] Gas sold or consumed by producers (*see* table 1, footnote 1.).
[3] Includes gas (mostly residue) blown to the air, but does not include direct waste on producing properties, except where data are available.
[4] Alabama, Florida, Maryland, Missouri, Nebraska, North Dakota, Tennessee, and Virginia.
[5] Alabama, Florida, Missouri, North Dakota, South Dakota, Tennessee, and Virginia.

STORAGE

Underground storage has been growing at an increasing annual rate. The total quantity of gas stored during 1951 was 51 percent above the 1950 figure, which in turn was 34 percent above the 1949 figure. West Virginia showed the largest increase in total volume stored in 1949–51. Also contributing to the large expansion were Michigan, Ohio, and Pennsylvania. Illinois, which previously had only negligible quantities in underground storage, in 1951 reported 1.6 billion cubic feet placed in storage as the result of a new project.

Digitized by Google

The American Gas Association reported that the number of underground storage projects increased from 125 in 1950 to 142 in 1951, and storage capacity from 774 to 916 billion cubic feet.

TABLE 4.—Natural gas stored underground in and withdrawn from storage fields, 1950–51, by State of location, in million cubic feet

State	1950			1951

Wyoming	1,685	1,097	588	1,424	1,720	−296
Total	229,752	175,260	54,492	347,690	209,428	138,262

MARKETED PRODUCTION [4]

Marketed production increased 16 percent to 6,282 billion cubic feet in 1950 and 19 percent to 7,457 billion in 1951.

Maryland and Nebraska reported a marketed production of natural gas for the first time in 1950, when pipeline connections were made to gas wells in these two States.

Increased marketed production in Colorado resulted from completion of a natural-gasoline plant at Rangely. In Wyoming increased marketed production was made possible by construction of sulfur- and natural-gasoline recovery plants and of a pipeline from Worland, Wyo., to Cabin Creek, Mont.

Most of the increased output of Kansas came from the Hugoton field. In New Mexico the development of the San Juan Basin boosted production. Most of the additional production of Mississippi came from the Baxterville and Gwinville gasfields. Pennsylvania's increased production resulted from the discovery and development of the Leidy gasfield.

Ten states showed a decline in marketed production over the 2-year period; these were Arkansas, Florida, Illinois, Michigan, Missouri, New York, North Dakota, Ohio, Utah, and Virginia. All except Florida also reported declines in 1949.

[4] *See* footnote 1, table 5.

[1] Comprises gas either sold or consumed by producers, including losses in transmission, amounts added to storage, and increases in gas in pipelines.
[2] Less than $500.

NUMBER OF WELLS

In 1951, 3,030 gas wells were drilled in the United States, 187 more than in the previous year. In New Mexico, 254 gas wells were drilled in 1951 compared with 88 in 1950 and 53 in 1949. This rapid rise was due primarily to development of the San Juan Basin. The number of gas wells drilled in Texas increased by 79 in 1951 but was still below the number drilled in 1949. The total number of producing wells, which increased by approximately 1,600 in 1950, was held to a much smaller increase in 1951 by indicated abandonment of a large number of wells in Pennsylvania and Ohio.

[3] Revised.

DEVELOPMENT AND PRODUCTION BY STATES [4]

Arkansas.—J. W. Sanders, chief engineer, Arkansas Oil and Gas Commission, reported that in 1951 gas production from the dry-gas fields in northwest Arkansas increased slightly to 8,182 million cubic feet from 8,017 million in 1950. Gas production from the oil and condensate wells in south Arkansas declined. Marketed production of all gas in 1951 was 44,656 million cubic feet compared with 48,047 million in 1950.

Five wildcat wells were drilled in northwest Arkansas, 1 of which resulted in a new discovery in Johnson County known as Low Gap field. Eight development wells were drilled in the northwest section, of which 6 were productive gas wells. Increasing interest was being shown in the northwestern part of the State.

California.—The Conservation Committee of California Oil Producers reported that the number of dry-gas well completions in 1951 was 11 less than in 1950. One new dry-gas field was discovered—Wild Goose field in Butte County. Of 31 new field wildcats drilled to find gas, only 1 was successful.

Reserves of both dry gas and oil-well gas continued to decline, as they have since 1948. Total production of oil-well gas in 1951 was the highest in California history; however, marketed production was only slightly higher than in 1950 because of the large increase in repressuring. Dry-gas production declined, largely because of the increased availability of gas brought in from Texas and New Mexico. By the end of 1951, imports of natural gas into California reached a total of approximately 815 million cubic feet per day.

[4] Based on latest available trade publications and reports from Federal and State agencies.

Digitized by Google

Colorado.—E. W. Henderson, U. S. Geological Survey, reported that 21 gas wells were completed in 1951, with a total initial open flow of 183 million cubic feet per day. Of this amount, 112 million was attributed to 1 completion at Barker Creek. New fields were discovered at Eskdale (Little Beaver Creek), Hell's Hole Canyon, High Line Canal, Padroni, and Twin Buttes (Douglas Pass).

A deeper pay zone was discovered in the Weber and Morgan formations in a deep test in the Thornburg field, and two shallower pay zones were found in the Fruitland and Pictured Cliffs sands in the Ignacio field. The Ignacio field in the San Juan Basin had considerable development but remained shut in, awaiting a pipeline connection. Wells on the Colorado side of the Barker Creek field, also in the San Juan Basin, were placed on production in October and contributed much of the increase in Colorado's gas production. Also, connected to pipeline outlets during 1951 were the 1950 Julesburg Basin discoveries—Armstrong, Lee, and Loveland fields.

Illinois.—A. H. Bell and L. L. Whiting, Illinois State Geological Survey, reported that 8 gas wells having a combined initial open flow capacity of 14 million cubic feet daily were completed in 1951. Five of these—3 in Louden and 1 each in Cottonwood and Herald fields—were being utilized. The others were shut in or abandoned owing to lack of market.

Marketed production of gas declined from 13,285 million cubic feet in 1950 to 11,425 million in 1951. Of this quantity, only 236 million cubic feet was used away from the producing fields.

Kansas.—J. M. Jewett of the Kansas Geological Survey reported that seven gas pools were discovered in Kansas during 1951: The Nippawalla pool in Barber County and the Brown West pool in Cowley County, producing from the Douglas group of the Pennsylvanian; the Theis pool in Clark County, the Wall pool in Harvey County, and the Graber North pool in McPherson County, producing from the Mississippian; the Greenwood pool in Morton County, producing from the Morrow group of the Pennsylvanian; and the Knoche pool in Stafford County, producing from the Viola limestone of the Ordovician period.

During 1951 the Hugoton field was reclassified as the Hugoton gas area and its producing area limited to gas produced from formations in the Chase group of the Permian system. The description of the former Hugoton field was adopted as the description of the Hugoton gas area. The eastern and western sides of the Hugoton gas area were each extended several miles. The discovery of gas and oil in the Light field in Seward County in 1950, along with the Greenwood-pool discovery in Morton County in 1951, indicated the possibility of future deeper development around the Hugoton gas area. Approximately 106,500 acres were added to the area, which totaled 2,255,000 acres as of the end of 1951. The Hugoton gas area produced 371 billion cubic feet from 2,595 gas wells in 1951, a 16-percent increase over 1950.

Kentucky.—C. D. Hunter, chief geologist, Kentucky-West Virginia Gas Co. reported that, during 1951, 254 wells were drilled for gas, of which 192 were productive and 62 dry holes. In the Big Sandy gas-field, which includes Pike, Floyd, Martin, Knott, Johnson, Magoffin, and Breathitt Counties, 151 gas wells and 25 dry holes were drilled, developing an initial daily open-flow capacity of 83 million cubic feet.

Digitized by Google

Marketed production increased from 73,316 million cubic feet in 1950 to 76,097 million in 1951. Most of the 1951 production came from the Big Sandy field, in which the Devonian black shales were the source of over 70 percent of the output.

In the old Artemus Himyar gasfield of Knox County, 23 gas wells were drilled, which developed an initial daily open flow of 29 million cubic feet.

In Scott County the shallow Trenton gasfield, discovered in 1950, was extended in 1951 into Grant County, and seven small wells of only local importance were drilled.

Louisiana.—The Louisiana Department of Conservation Petroleum Activity Report for 1951 reported that 244 gas wells were completed in 1951 compared with 394 in 1950. Thirteen new gasfields were discovered, whose names and locations, by parishes, are: Basile and Northwest Branch in Acadia, Sentell in Caddo, South Pecan Lake in Cameron, Lake Borgne in Orleans, Main Pass Area Block 35 in Plaquemines, Washington in St. Landry, Atchafalaya Bay and Patterson in St. Mary, Ship Shoal Area Block 23 and South Pelto Area Block 20 in Terrebonne, Angie in Washington, and Grosse Tete in West Baton Rouge.

Only one of these fields is in north Louisiana. Gas production from south Louisiana in 1951, as the result of several recently completed market outlets, increased 78 percent and approximated that of north Louisiana.

Marketed production for the whole State was 1,054 billion cubic feet in 1951, 27 percent over 1950.

Maryland.—Joseph T. Singewald, Jr., director of the Maryland Department of Geology, Mines and Water Resources, reported that at the close of 1951, 23 gas wells were producing in the Mountain Lake Park field in Garrett County. The field was producing along a 7-mile strike length, the full extent of which had not been determined. The Mountain Lake Park field is a structural high on the Deer Park anticline that has a strike length exceeding 40 miles across Garrett County.

Marketed production in 1951 was 3,422 million cubic feet compared with 373 million in 1950, the first year of production.

Michigan.—F. G. Pardee and W. L. Daoust, Geological Survey Division, Michigan Department of Conservation, reported no outstanding natural-gas developments in Michigan during 1951. Forty-three wells were completed in gas-storage reservoirs, and 20 new dry-gas wells were completed. The storage wells were drilled principally in the Austin Reservoir in Mecosta County and in the Freeman-Lincoln Reservoir of Clare County.

New gas wells were drilled in Muskegon, Mecosta, Missaukee, Kalkaska, Montcalm, Oceana, Newaygo, and Osceola Counties. The initial daily production for the new gas wells totaled 31,733 thousand cubic feet.

There were 10 storage fields at the end of 1951, with others scheduled to be converted to reservoir fields in the near future.

Mississippi.—Three wildcat gas wells and 23 development wells were completed in Mississippi in 1951. The southwest portion of the State continued to receive the bulk of the exploratory work, accounting for two of the gas discoveries.

Digitized by Google

A revival of interest in possible production from Paleozoic rocks in northeastern Mississippi was occasioned by reworking of an abandoned wildcat in southwest Monroe County. It had been abandoned in 1941, but persistent gas seepages since that time led to the reworking. The well blew out during the reworking and had not been completed at the end of 1951.

Interest in production from the Smackover was strengthened by completion of a gas and condensate well in the Tirsley field in Yazoo County. The gas had a very high sulfur content.

Missouri.—Frank C. Greene, district geologist, Missouri Division of Geological Survey and Water Resources, reported that there were no new gas discoveries in Missouri in 1951. A pipeline was laid to the reactivated East Smithville gasfield in Clay County. A small line was laid from the Lisle area in Cass County to Drexel, and arrangements had been made for a line into the small field south of Harrisonville in Cass County.

Marketed production dropped to 14 million cubic feet in 1951 from 21 million in 1950.

Montana.—E. W. Henderson, U. S. Geological Survey, reported that the only gas discovery in Montana in 1951 was a small well at Battle Creek. Extension wells were drilled at Apex, Bears Den, and Whitlark. In all, 27 producing wells were completed, with an initial open flow of 82 million cubic feet per day.

The towns of Havre and Chester were connected by pipeline to the Utopia field. A 16-inch line was completed from the international boundary to the natural-gasoline plant at Cut Bank for the purpose of importing gas from Alberta, Canada, but the line was not placed in operation until approval of the importation was granted in 1952.

Production from the Cut Bank and Regan fields increased by about 1,600 million cubic feet in 1951, while production from the Bowdoin and Cedar Creek fields decreased 4,500 million owing to substitution of gas piped from Worland, Wyo.

Nebraska.—Fourteen gas wells were completed in Nebraska in 1951—9 in Duel County and 5 in Cheyenne. In 1950, only one gas well was successful in Duel County. Three of the 1951 wells were wildcats. Wildcats northeast and southwest of production in the Big Spring field, Duel County, indicate an approximate field length of 6 miles. A southeast extension of the Southwest Sidney field was successful 2¼ miles from the discovery well.

New Mexico.—R. E. Canfield, U. S. Geological Survey, reported that the 451-mile, 24-inch natural-gas pipeline of El Paso Natural Gas Co. from the San Juan Basin to Toprock, Ariz., was completed in August 1951. By reason of this completion, drilling activities in the basin were accelerated. There were 92 gas-well completions in the New Mexico portion of the basin in 1951. Most of the wells were in the Blanco-Mesaverde area. Four new gasfields were discovered during the year.

In southeastern New Mexico, 28 gas wells were completed in Lea County and one in Eddy County.

New York.—W. L. Kreidler, senior geologist, New York Geological Survey, reported that very little exploratory drilling for new gas supplies was carried on in New York during 1951. An attempt was being made to revitalize the Sandy Creek field by acidization. This

Digitized by Google

field produces from the Trenton. An estimated 51 wells were drilled in the Medina gas area: 8 dry holes, 29 storage wells, and 13 producing wells in extensions of known fields. One Medina wildcat was drilled in Bennington Township, Wyoming County, and produced 400 thousand cubic feet per day.

In the Oriskany gas area, 1 productive wildcat and 1 dry hole were drilled in Cattaraugus County. Three storage wells were drilled in the Dundee field, and the South Addison field was being prepared for storage by reconditioning the old wells.

Marketed production in 1951 was 3,214 million cubic feet, the Medina producing roughly 70 percent and the Oriskany 30 percent.

North Dakota.—Wilson M. Laird, State geologist, North Dakota Geological Survey, reported that marketed production of natural gas in 1951 was 456 million cubic feet, 152 million less than in 1950. All of the gas was produced from the Baker-Glendive gasfield, which extends into the southwestern corner of North Dakota. No activity in gas-well drilling was reported. The first oil well in the State was completed in 1951 at Beaver Lodge in Williams County. It had a gas-oil ratio of 1,100 to 1,300 cubic feet per barrel from the Madison limestone.

Ohio.—R. L. Alkire, chief of the Oil and Gas Section, Ohio Geological Survey, reported that 420 gas wells were completed in 1951, with an average initial open-flow capacity of 506 thousand cubic feet per day. Extensions to known pools in 1951 added 9,500 proved acres. Approximately 1,900 acres were proved as the result of the discovery of three new pools: (1) In northwestern Jefferson Township, Tuscarawas County (Berea sand); (2) in southwestern Knox Township, Holmes County (Newburg sand); (3) in Worthington Township, Richland County.

The possibility of a major new Oriskany-sand field may result from 2 discovery wells, approximately 20 miles apart, drilled in Washington County: The B. H. Putnam-Lamp No. 1, lot 66, Belpre Township, and the B. H. Putnam-Arnold No. 1, lot 60, Watertown Township. The Oriskany sand lies at an average depth of 4,200 feet and has an initial rock pressure near 1,675 pounds per square inch.

Oklahoma.—Elmer Capshaw, Oklahoma Corporation Commission, reported that the most significant development in the gas industry in Oklahoma had been the continued shift of Oklahoma gas distributors from dry natural gas to casinghead gas, caused by rising field prices of dry gas.

The last large undeveloped acreage of the Guymon-Hugoton field in Texas County was in the process of being developed and was expected to have 125 to 150 wells. The Oklahoma Guymon-Hugoton produced 154 billion cubic feet of gas in 1951.

Pennsylvania.—J. G. Montgomery, Jr., vice president, United Natural Gas Co., reported that the more important developments in Pennsylvania in 1951 were intensive development of the Leidy pool, discovery of gas in the Driftwood pool in Cameron County, and completion of the two Cambro-Ordovician tests.

The Leidy gasfield in Clinton County underwent intensive development. Fifty-one producing wells with an average initial open flow of 10 million cubic feet per day and 12 dry holes were completed. One well, the H. E. Finnefrock No. 1, was completed with an initial open flow estimated at 145 million cubic feet of gas per day. This

Digitized by Google

was probably the largest gas well ever drilled in the Appalachian area. By the end of 1951, the pool had been developed approximately 9 miles in length and 1½ miles in width. The limits of production have probably been established on the southwest end of the structure, but not on the northeast end. It was estimated that the Leidy pool produced at the rate of 150 million cubic feet of gas per day during 1951. The life of the pool was expected to be relatively short because of the intensified competitive exploitation.

One productive gas well and 1 dry hole were completed in the Oriskany sand in the Driftwood pool in Cameron County. Completion of the producing well resulted in much activity, and by the end of 1951, 26 wells were being drilled and 11 locations made. The discovery well had an initial open flow of approximately 4 million cubic feet per day and an initial rock pressure of 3,825 pounds per square inch.

Two Cambro-Ordovician tests were completed in 1951; both were dry holes. One in Lycoming County on the Nippenose Dome had a small show of gas in the Upper Cambrian. The other, in Sullivan County, penetrated the upper Ordovician shales before being abandoned. This well was drilled to a depth of 12,343 feet with rotary tools and is one of the deepest wells in the Appalachian area. A third well, being drilled in Bedford County, had an estimated 600,000 cubic feet in the Beekmantown and by the end of 1951 had reached a depth of 8,979 feet.

In addition, 238 productive shallow-sand gas wells were drilled with a total initial open flow of 32 million cubic feet per day.

Texas.—Proved reserves of natural gas in Texas increased over 3 trillion cubic feet in 1951. Most of this increase was in the reserves of dissolved gas. Total gas-well completions increased from 647 in 1950 to 726 in 1951.

In the Panhandle district over 300 development gas wells were drilled, 5 times as many as in 1950. This has resulted in almost complete development of the Hugoton field, apparently defining its limits. About half of the wells were drilled in Sherman County.

In south Texas most of the development drilling was in the lower Oligocene. Exploratory drilling in this trend did not discover anything by 1951 that could be classed as a major reserve. The Blackjack field in Aransas County was discovered by Western Natural Gas Co. St. Charles Ranch No. 13, with an open flow of 86 million cubic feet.

The most important discovery in the upper Gulf-coast district appeared to be the Wadsworth gas-condensate field in Matagorda County. The discovery well was drilled to 14,524 feet, the deepest well drilled in the district in 1951. It produced from the Frio at 11,275 to 11,285 feet. The search for deeper producing reservoirs would necessitate leasing lands previously abandoned after shallow tests.

Development drilling in east Texas declined in 1951, whereas exploratory drilling increased substantially. New field discoveries showed a trend toward increasing gas-condensate rather than oil reserves.

In west-central Texas important gas reserves were indicated in Callahan, Coleman, Eastland, Parker, and Stephens Counties. Parker was outstanding, with three new gas discoveries producing from the Strawn. There were no oil discoveries in 1951.

Digitized by Google

Utah.—E. W. Henderson, U. S. Geological Survey, reported that one new gasfield was discovered at Clear Creek in Carbon County. The well had an initial daily open flow of 7.5 million cubic feet from the Ferron sandstone of the Mancos shale. This well is near the Gordon Creek field, where carbon dioxide was discovered in 1948. More drilling in the area was expected. An oil well in the Red Wash field in Uintah County was recompleted as a gas producer.

The only commercial gas production, as usual, was from the Clay Basin field. Carbon dioxide was produced commercially from the Farnham field.

Virginia.—William M. McGill, State geologist, Virginia Geological Survey, reported that in the Appalachian Plateaus section tests for natural gas were drilled in Buchanan, Dickenson, and Wise Counties and that in the Appalachian Ridges and Valley province tests for gas were drilled in Rockingham County. Of 27 tests completed, 11 were dry holes, and 16 were completed as potential producers (Buchanan County, 6; Dickenson County, 9; Rockingham County, 1). The potentially productive gas wells range in depth from 2,300 to 7,000 feet. The gas was encountered mainly in sandstone horizons of the lower Mississippian but was also found in overlying Pennsylvanian sandstone and in underlying Devonian shale.

Indications were that approximately 60 million cubic feet per day could be obtained from the completed and capped wells in Buchanan and Dickenson Counties. Commercial production in 1951 was obtained only from the Early Grove field in Scott and Washington Counties. Gas produced in other fields was used only for drilling operations. Marketed production in 1951 was 64 million cubic feet.

West Virginia.—R. C. Tucker, assistant State geologist, West Virginia Geological and Economic Survey, reported that 463 gas wells were completed in 1951—46 more than in 1950. These had a total initial daily open flow of 356 million cubic feet. The average initial open flow of gas wells was 757 thousand cubic feet compared with 1,079 thousand in 1950. The greatest number of gas-well completions was made in Wayne County with 61, Lincoln County with 58, and Mingo County with 57. Preston County, with 9 completions, had the largest average initial daily open flow (4,471 thousand cubic feet).

Wildcat discoveries by County and producing horizon include Wood County, Berea; Boone County, Big Lime; Mingo County, Big Lime; Wirt County, Oriskany; Webster County, Maxton Sand (first production for this county); and Pleasants County, Salt Sand.

Wyoming.—E. W. Henderson, U. S. Geological Survey, stated that 23 gas wells were completed in 1951 with a total initial daily production of 74 million cubic feet. Only one was an exploratory well—a shallow test at Fish Creek in Natrona County, and this was not considered a commercial discovery.

The Heart Mountain field in Park County was connected to a pipeline outlet and became a commercial producer. Excess gas from the Sand Creek field in Washakie County was delivered via pipeline to Worland for transmission with other local gas to Cabin Creek, Montana. Eighty-six miles of line was laid from the Big Sand Draw field to Rawlins, Wyo., to increase the gas supply of the Rawlins-Laramie area. The Salt Wells field in Sweetwater County was tied into the

Digitized by Google

Mountain Fuel Supply Co. system supplying the Salt Lake City-Ogden area in Utah.

Increased production was due mainly to the larger pipeline deliveries from the Worland and Church Buttes fields.

INTERSTATE SHIPMENTS AND EXPORTS

Interstate shipments and exports of natural gas increased by 535.7 billion cubic feet in 1950 and by 699.2 billion in 1951. Interstate shipments in 1949 were 37 percent of marketed production; they increased in 1950 to 40 percent and in 1951 to 43 percent of marketed production. Interstate shipments increased from all Census regions in 1950, and in 1951 only the South Atlantic and East North Central regions showed declines. The percentage of marketed production shipped interstate showed an upward trend during this period in Louisiana, New Mexico, and Texas. In Mississippi and Oklahoma the percentage shipped out of State remained steady and in Kansas declined.

The East North Central region remained the largest consumer of interstate natural gas during the 1949–51 period and also showed the largest increase during this period. The Pacific and Middle Atlantic regions showed the largest rate of increase. Completion of pipeline facilities to the Philadelphia and New York City areas accounted for much of the increase in the Middle Atlantic region. Also experiencing a steady rise in the consumption of interstate gas was the East South Central region, more particularly Alabama and Tennessee.

Exports to Mexico remained around 20 billion cubic feet per year for the 2-year period. Exports to Canada increased sharply from 226 million cubic feet in 1949 to 3,170 million in 1950 and then expanded less rapidly to 3,630 million in 1951.

PIPELINES

In 1951 the Federal Power Commission authorized natural-gas pipeline projects to cost $471,383,000 and including 5,791 miles of pipeline. The corresponding figures for 1950 were $632,201,000 and 7,618 miles (revised).

Three new major pipelines were completed during 1951. The Texas-Illinois Natural Gas Pipeline Corp. constructed a line from the lower Gulf coast of Texas to the Chicago area. The Trunkline Gas Supply Co. completed a line from the lower Texas Gulf coast to Tuscola, Ill. where it connects with the line of Panhandle Eastern Pipeline Co. The El Paso Natural Gas Co. completed its line from the San Juan Basin in northwest New Mexico to the California border.

[1] Includes exports as follows: 1950, total, 25,727 million cubic feet; to Mexico, 22,557 million; to Canada, 3,170 million; 1951, total 24,163 million; to Mexico, 20,533 million; to Canada, 3,630 million.
[2] Includes amounts consumed, stored, and lost in transmission.

CONSUMPTION

Consumption of natural gas in the United States in 1951 was 7,103 billion cubic feet. Increases of 831 billion cubic feet and 1,076 billion were recorded in 1950 and 1951, respectively. The largest rate of increase was experienced in the residential category.

Residential and Commercial.—The consumption of natural gas for residential use increased 21 percent in 1950 and 23 percent in 1951 to

Digitized by Google

1,475 billion cubic feet in the latter year. Residential use as a proportion of total consumption, which had been rising steadily since the close of World War II, increased from 16.5 percent in 1946 to 20.8 percent in 1951. Residential consumption increased in all reporting States over the period 1949 to 1951. Largest increases took place in Michigan, New York, Ohio, and Pennsylvania. In 1951 Ohio assumed first place as a consumer of gas for residential use, a position long held by California. The increased residential use of natural gas had not been limited to regions where the availability of natural gas was relatively recent; the West South Central region (Arkansas, Louisiana, Oklahoma, and Texas) showed a 17-percent gain from 1950 to 1951. The number of consumers of natural gas for residential use increased from 14.7 million in 1949 to 16.9 million in 1950 to 21.4 million in 1951. The residential consumers who received natural gas as a component of mixed gas are included in these figures, and the natural gas they consumed is included in the natural-gas consumption figures. Eliminating this use in mixed gas, the average annual residential consumption of straight natural gas per consumer rose from 77,500 cubic feet in 1949 to 83,600 in 1950 and 86,700 in 1951.

[1] Includes natural gas mixed with manufactured gas.

Digitized by Google

Commercial consumption increased by 40 billion cubic feet to 388 billion in 1950. This was 6.4 percent of the total United States consumption, slightly less than in 1949. In 1951 commercial consumption increased at a faster rate than overall consumption and accounted for 6.5 percent of the total.

Treated for Natural Gas Liquids.—In 1950, 5,342 billion cubic feet of natural gas was treated at natural-gasoline and cycle plants, an increase of 686 billion cubic feet over 1949. In 1951, 6,203 billion cubic feet was treated. In the 5-year period 1946–51 the percentage of gross withdrawals treated rose from 59 percent to 64 percent. Average yield of natural-gas liquids was 1.43 gallons per thousand cubic feet of gas treated in 1950 and 1.39 gallons per thousand cubic feet in 1951. The total liquid volume of 181,961 thousand barrels recovered in 1950 is equivalent to approximately 260 billion cubic feet. This shrinkage is included in the field use of gas.

The volume of gas treated increased in all States in 1951 except Illinois, Michigan, New York, and Pennsylvania. A natural-gasoline plant operated in Nebraska in 1951 for the first time.

TABLE 11.—Natural gas treated at natural-gasoline and cycle plants in the United States, 1947–51, by States, in million cubic feet

Wyoming	22,261	29,998	32,333	39,164	45,139
Total	4,070,150	4,393,500	4,656,142	5,341,804	6,203,070

Field.—Field use of natural gas increased 12 percent in 1950 and 21 percent in 1951. Since 1938 field use has not increased as fast as marketed production, and this continued to be the case (except for Texas) in 1951.

Carbon-Black Manufacture.—The use of natural gas for the production of carbon black in 1950 declined 17,040 million cubic feet to 410,852 million and returned to approximately the 1949 level in 1951. Use by plants in the Panhandle region of Texas declined by 33,587 million cubic feet in 1950 and remained there in 1951. Eighty-six percent of the gas used in manufacturing carbon black in 1950 and 85 percent in 1951 were used to make channel-type blacks. Use of this black has been declining, as new furnace-type blacks have been developed and higher percentages of synthetic rubber are used.

Petroleum Refineries.—The use of natural gas as fuel at petroleum refineries increased 8 percent in 1950 and 18 percent in 1951. California and Texas showed the largest increases, California in 1951 returning to the 1948 level of consumption after dropping in 1949. Natural gas was used for the first time at refineries in Tennessee and New Jersey, and a large increase in the use by Pennsylvania refineries was reported. Natural gas supplied 36.9 percent of total refinery fuel in the United States in 1951 and 34.7 percent in 1950 compared with 33.2 percent in 1949.

Electric Utility Plants.—The use of natural gas as fuel at electric-utility plants increased 14 percent in 1950 and 21 percent in 1951. Electric generation (excluding hydroelectric generation) increased by 16 percent in each of these years. Increases in gas used took place in most States; there were especially large relative increases in Georgia, Mississippi, New Jersey, New York, and Pennsylvania.

Portland-Cement Plants.—The use of natural gas as fuel at portland-cement plants increased 15 percent in 1950 and 6 percent in 1951. The production of portland cement correspondingly increased 8 and 9 percent. The use of gas was reported for the first time by plants in Arizona, Mississippi, and Montana.

Natural-Gas Pipelines.—Starting in 1950, data were collected on the use of natural gas as a fuel at natural-gas-pipeline compressor stations. Previously this gas was reported under "Other industrial." Because 1950 was the first year such figures were reported, this figure for 1950 may not be entirely comparable with that for 1951. In 1951 the quantity of gas used for this purpose was 192 billion cubic feet—about 6 percent of the industrial use exclusive of field and carbon black.

Other Industrial.—In 1951, "Other industrial" use increased 14 percent. This is a smaller rate of increase than was shown by most of the other classes of consumers for 1951. Texas, with a 10-percent increase, was below the national average.

Mixed Gas.—The overall volume of natural gas distributed as mixed gas did not increase significantly in 1950, but there was a sharp shift in the location and number of consumers receiving mixed gas. Missouri in 1950 had no distribution of mixed gas, all distributors having converted to straight natural by the end of 1949. In 1951 the volume of natural gas used with manufactured gas increased sharply, primarily as the result of completion of a pipeline to the New York City area. Iowa, Kentucky, and Nebraska reported no natural used in mixed gas in 1951.

The consumers and the volumes reported in table 13 are included in the general-consumption tables (tables 8–12) for natural gas.

[1] Included in tables for the consumption of natural gas (tables 8–12).

PRICES

The average value at wells for natural gas in the United States in 1950 was 6.5 cents per thousand cubic feet, an increase of 0.2 cent from 1949. Most of the larger producing States recorded increases of from 0.1 to 0.2 cent per thousand. Kansas showed the largest gain, from 5.4 to 6.6 cents per thousand, partly as a result of enforcement of a minimum-price ruling upheld by the United States Supreme Court in 1950.

In 1951 the average wellhead value of natural gas increased 0.8 cent to 7.3 cents per thousand cubic feet. This was the sharpest increase yet recorded in 1 year. Increases were general through all the producing States. Increases in the major producing States of the Southwest (Mississippi excepted) ranged from 0.4 to 1.5 cents per thousand cubic feet compared with 0.1 to 0.2 cent in 1950. In Illinois, Indiana, Michigan, and Pennsylvania, which showed declines in 1950, the rise in 1951 was even larger.

Residential average values showed scattered plus and minus changes by States in 1950, and in 1951 the majority of the changes were declines. Industrial average values, on the other hand, while showing

Digitized by Google

a predominance of negative changes in 1950, showed increases in most States in 1951. The increases in average value at point of consumption then must be attributed more to the increasing proportion of high-value sales—that is, residential and commercial—than to the increase in unit price of a particular sale. Also, the increased volume of gas distributed after long-distance transmission in regions where the unit value was high tended to raise the national-average value at points of consumption.

WORLD REVIEW

Canada.—Gross production of natural gas in the Province of Alberta in 1951 was 85.4 billion cubic feet compared with 75.6 billion in 1950. The Petroleum and Natural Gas Conservation Board of Alberta reported that Alberta's proved reserves of natural gas at the end of 1951 were 6.8 trillion cubic feet. The board estimated that 6.5 trillion cubic feet would be required to meet the needs of Alberta for the next 30 years and expected new reserves to be found at the rate of 1 trillion cubic feet per year for 8 to 10 years.

Italy.—The production of natural gas in Italy again doubled in 1951, reaching 34 billion cubic feet. Domestic consumers used about 4 percent of the production, 12 percent was used for motor-vehicle fuel, and 81 percent went to industrial consumers. At the end of 1951, there were 950 miles of natural-gas pipeline in Italy.

Mexico.—Gross production of natural gas in Mexico in 1951 was approximately 80 billion cubic feet. The Poza Rica field produced most of this gas. Pending completion of repressuring facilities here large quantities of gas were being flared.

[1] Preliminary or estimated figures.
[2] Data not available.
[3] American and British Zones.
[4] April–December.
[5] January–June.
[6] Beginning 1945, industries under control of the National Resources Commission.
[7] Less than 500,000 cubic meters.
[8] Excluding U.S.S.R., where natural-gas consumption was last reported as 1,400 million cubic meters in 1936.
[9] Revised.

Venezuela.—Gross production of natural gas in Venezuela in 1951 was approximately 600 billion cubic feet. Only 1 percent of this was utilized away from the producing fields.

The natural-gas pipeline from Las Mercedes and Tucupido to Caracas was completed, and a line was started from Anaco to Puerto La Cruz.

Natural-Gas Liquids

By D. S. Colby, E. M. Seeley, A. T. Coumbe, and I. F. Avery

GENERAL SUMMARY

PRODUCTION of natural-gas liquids in 1951 increased 13 percent over 1950 to 205 million barrels. In 1950 production had increased 16 percent over 1949. The LP-gas [1] portion of this output showed the highest rate of increase in 1951—20 percent. Production of natural gasoline and of finished gasoline and naphtha also increased, while that of "other products" (condensate, kerosine, distillate fuel, etc.) declined.

In 1951, 6,203 billion cubic feet of gas was treated, and the average recovery of all liquids was 1.39 gallons per thousand cubic feet. At the end of 1951 operable plant capacity totaled 812 thousand barrels per day at 521 plants.

Total demand for natural-gas liquids in 1951 was 206 million barrels—13 percent above the previous year. Shipments to refineries increased 8 percent; LP-gas sales for fuel increased 17 percent, and a 42-percent increase took place in the use of LP-gases for chemical production.

Total stocks at plants, terminals, and refineries increased 831 thousand barrels during 1951, as a slight decrease in stocks of LP-gases was more than counterbalanced by increases for natural gasoline and other products.

The total value of natural-gas liquids produced increased from $420 millions in 1950 to $508 millions in 1951. The average value per gallon rose in 1951 to 5.9 cents after dropping from 6.1 cents in 1949 to 5.5 cents in 1950.

Exports of natural gasoline and liquefied gases (LP-gases and LR-gases) increased in 1951 and together totaled 3,718 thousand barrels compared with 2,612 thousand barrels in 1950.

RESERVES

The American Gas Association Reserves Committee estimated proved recoverable reserves of natural-gas liquids in the United States at the end of 1951 to be 4,725 million barrels. The estimated increase in reserves during the year was the second largest for any year since the committee began estimating reserves in 1947. The percentage of reserves existing in dissolved gases increased from 26 percent in 1947 to 34 in 1951, that is, the major additions to reserves were of liquids in dissolved gases. In 1951 the major additions to reserves took place in Texas, Louisiana, New Mexico, Oklahoma, and West Virginia. California showed the largest decrease in reserves for any State during the year owing to revision of reserve estimates. States whose reserves of natural-gas liquids had declined during each of the years 1949, 1950, and 1951 were Arkansas, Colorado, Kentucky, Mississippi, Montana, Pennsylvania, and Utah.

[1] Liquefied petroleum gas. Does not include LR- (liquefied refinery) gases except where indicated.

PRODUCTION

The production of natural-gas liquids in 1951 totaled 204,754,000 barrels, an increase of 13 percent over 1950 compared with a 16-percent increase in 1950 over 1949. Natural gasoline and LP-gases continued the rapid increases recorded in 1950; the increase in production of finished gasoline and naphtha was less than that in 1950, and the output of "other products" declined from the 1950 figure. The percentage changes in production for the various products in 1951 compared with 1950 were: Natural gasoline, +9 percent; LP-gases, +20 percent; finished gasoline and naphtha, +10 percent; other products, −3 percent.

[1] Comprises natural gasoline, LP-gases, and condensate.
[2] Not allocated by types, but occurring principally in column shown.

The production of LP-gases exceeded that of natural gasoline for the first time in 1951.

[1] Includes condensate, kerosine, distillate fuel, etc.
[2] A producer operating in more than 1 State is counted but once in arriving at total for United States.
[3] Less than 500 barrels or $500.
[4] Colorado, Utah, and Nebraska combined under "Undistributed," to avoid disclosure of individual operations.
[5] Michigan included with Illinois.
[6] Includes 36,627 million cubic feet from transmission lines previously treated in another State.
[7] New York included with Pennsylvania.

REVIEW BY STATES

California.—The total production of natural-gas liquids in California increased 4 percent in 1951, the same rate of increase as in 1950. LP-gas production increased considerably, but the output of "other products" declined.

Louisiana.—The production of natural-gas liquids in Louisiana increased 8 percent in 1951 to 22,482,000 barrels. Output in the Gulf coast area of Louisiana, which had been declining slowly for several years, increased 10 percent in 1951. Natural-gasoline production in that area decreased but was more than offset by increases in production of LP-gases, finished gasoline and naphtha, and other products.

Oklahoma.—The production of natural gasoline and LP-gases in 1951 increased by 19 and 20 percent respectively, maintaining the rapid rise of recent years. The output of finished gasoline and naphtha and of other products also increased, but these only accounted for about 2 percent of the total production of natural-gas liquids.

Texas.—Bureau of Mines production district boundaries were revised in 1951 to coincide with Texas Railroad Commission districts and to provide a separate breakdown of West Texas. The Gulf coast comprises Railroad Commission districts 2 and 3; West Texas—districts 7c and 8; East Proper (East Texas field)—part of district 6; and Panhandle—district 10.

The percentage increase in the production of natural-gas liquids in Texas was less in 1951 than in 1950 but still exceeded the national average. The output of natural gasoline increased 13 percent and of LP-gases, 23 percent. Texas in 1951 provided 53 percent of the natural-gas liquids produced in the United States compared with 52 percent in 1950.

Other States.—As in 1950, Illinois, Michigan, and New York reported decreased production of natural-gas liquids. In addition, in 1951, output declined in Mississippi. Nebraska produced for the first time in 1951. Wyoming showed an above-average gain, and opening of the extraction plant on the Tennessee Gas Transmission Co. pipeline in Kentucky sharply increased that State's output at the end of 1951.

YIELDS, PROCESSES, AND NUMBER OF PLANTS

Cycle Plants.—In 1950, 1,216,405 million cubic feet of gas was treated at cycle plants to recover 42,730 thousand barrels of liquid products. In 1951, 1,223,459 million cubic feet was treated to recover 43,911 thousand barrels. The average yields for these 2 years were 1.48 gallons per thousand cubic feet in 1950 and 1.51 gallons in 1951.

Yields.—The average yield of all natural-gas liquids, after rising slowly since 1943, declined 0.04 gallon per thousand cubic feet in 1951 to 1.39 gallons per thousand cubic feet. The yield of LP-gases, however, continued its steady increase; the yield of natural gasoline

Digitized by Google

and other products declined more sharply than in previous years. This indicated that a rising proportion of the drier gases was being treated. The yield of LP-gases in 1951 was 0.59 gallon per thousand cubic feet, up 0.02 gallon from 1950.

[1] Includes 21 plants manufacturing LP-gases in 1950 and 9 plants in 1951.
[2] Includes combination of absorption process with compression and charcoal processes. Includes 262 plants manufacturing LP-gases in 1950 and 279 plants in 1951; 3 charcoal plants in West Virginia and Ohio producing 13,000 barrels in 1950 and 2 charcoal plants producing 45,000 barrels in 1951.
[3] Includes 37 plants manufacturing LP-gases in 1950 and 35 in 1951.
[4] Includes 962,000 barrels of field condensate.
[5] Drip gasoline.
[6] New York included with Pennsylvania.
[7] Included under "Undistributed" to avoid disclosure of individual operations.
[8] Michigan included with Illinois.

Digitized by Google

The average value of liquid products recovered increased from 7.9 cents per thousand cubic feet treated to 8.2 cents in 1951. The rise was due almost entirely to higher prices and not to changes in yield.

Production by Processes.—The number of plants operating in 1950 remained unchanged from 1949 at 550, the reduction in the number of operating compression plants being offset by an increase in the number of absorption and cycling plants. The production of natural-gas liquids at each of the three major types of plants was greater in 1950 than in 1949.

In 1951 the number of operating plants declined to 521, primarily because of further reduction in the number of operating compression-type plants. Production from compression-type plants declined in 1951, but that from absorption and cycle plants increased.

MARKET DEMAND—SHIPMENTS

Total demand for natural-gas liquids at plants and terminals was 206 million barrels in 1951, 12 percent more than in 1950. Demand exceeded 1950 for all products except condensate.

Shipments to Refineries.—Shipments of natural-gas liquids to refineries increased 8 percent in 1951. The largest gains percentage-wise were made in the shipments of isopentane and of "other LP-gas mixtures." Regionally, the Texas Gulf and the Indiana-Illinois-Kentucky districts showed the largest increases in the utilization of natural-gas liquids at refineries. East Coast and California showed large declines. The average natural-gas liquid content of refinery gasoline declined to 9.0 percent in 1951 from 9.5 percent in 1950.

TABLE 6.—Percentage of natural-gas liquids in refinery gasoline in the United States, 1947–51, by Bureau of Mines refinery district

Year	East Coast	Appalachian	Indiana, Illinois, Kentucky	Oklahoma, Kansas, Missouri	Texas Inland	Texas Gulf Coast	Louisiana Gulf Coast	Arkansas, Louisiana Inland	Rocky Mountain	California	Total
1947	0.8	2.0	5.5	7.7	22.6	8.8	5.3	10.3	3.9	17.4	8.7
1948	.8	2.4	5.0	8.9	25.0	8.3	4.8	7.1	3.8	17.2	8.5
1949	1.5	2.0	5.3	9.5	27.6	8.5	6.0	7.5	4.5	18.4	9.1
1950	3.5	1.7	5.0	8.3	26.0	10.7	5.9	13.8	4.1	19.0	9.5
1951	2.6	1.7	5.1	8.9	23.1	11.1	5.3	12.4	4.3	16.1	9.0

"Direct" Sales.—Direct sales from plants increased more rapidly than sales to refineries. The largest gain was in sales of LP-gases for chemical use, which increased 42 percent to 12,230,000 barrels. Sales of LP-gases for fuel increased 17 percent, and sales of natural gasoline to jobbers rose by 38 percent.

In the period 1949–51 tank trucks grew in importance as a mode of transport of natural gasoline and allied products at the expense of rail tank car. The percentage of total output transported by tank truck rose from 21 percent in 1949 to 24 percent in 1951, while tank cars handled 24 percent in 1949 and 21 percent in 1951. Pipelines and barges held their position virtually unchanged at 51 and 2 percent, respectively, for 1951.

SALES OF LP-GASES [2]

A sharp upward trend in sales of LP-gases, evident in 1950, continued into 1951, when deliveries to consumers were 21 percent over the 1950 total, which in turn had been 23 percent above 1949 requirements. The market for this liquid fuel virtually doubled in 4 years, as its advantages for both domestic and industrial uses, as well as for fueling internal-combustion engines, became more widely known. Furthermore, its rapidly growing use as raw material by both synthetic-rubber and chemical-manufacturing plants also helped to rapidly expand the demand. Exports of LP-gases had likewise mounted sharply with increases over the preceding year of 17 percent in 1949, 27 percent in 1950, and 29 percent in 1951, according to records of the Bureau of the Census, United States Department of Commerce.

TABLE 9.—Sales of LP-gases [1] in the United States, 1947–51, by type of gas

Year	Butane		Propane		Butane-propane mixture		Total	
	Thousand gallons	Percent of total	Thousand gallons	Percent of total	Thousand gallons	Percent of total	Thousand gallons	Increase over previous year, percent
1947	398,635	18.0	863,686	39.1	947,476	42.9	2,209,797	29.8

1951	708,989	16.8	2,418,790	57.2	1,099,496	26.0	4,227,275	21.7

[1] Data include LR-gases.

TABLE 10.—Sales of LP-gases [1] in the United States, 1947–51, by uses, in thousands of gallons

Year	Domestic and commercial	Chemical	Synthetic rubber	Industrial	Gas manufacturing	Internal combustion	All other	Total
1947	1,150,538	414,267	201,535	173,601	169,332	99,786	738	2,209,797
1948	1,473,289	524,350	225,641	180,518	237,638	92,941	2,424	2,736,801
1949	1,627,550	544,886	177,850	162,197	239,210	77,981	6,925	2,836,599
1950	[2] 2,022,464	[2] 624,468	228,485	217,078	251,694	129,818	8,560	3,482,567
1951	2,166,813	844,507	374,864	262,102	281,692	289,991	7,306	4,227,275

[1] Data include LR-gases. [2] Revised.

A survey of sales of LP-gases by States, first attempted for 1950, was repeated for 1951, so that a more detailed review of State markets on a comparative basis, is now available.

The market for LP-gases showed important increases in all parts of the country in 1951, except in district 1. Most of the liquid gases sold in that area are consumed for domestic and commercial fuel and that particular use registered only a nominal gain in 1951 over the 1950 total. Over 40 percent of the 1951 sales were reported from district 3, and there the expansion in the demand was outstanding—35 percent over the 1950 total—due mostly to much greater requirements for

[2] LP-gases, as used in this section, include LR-(liquid refinery) gases as well. E. T. Knudsen, Chief, Petroleum Statistics Branch, Bureau of Mines, Region III, Los Angeles, Calif., made the survey and compiled the sales statistics for district 5. Districts are those of the Petroleum Administration for War.

raw materials and solvents going to synthetic rubber and chemical manufacturing plants. District 2 was the second most important market for these liquid gases, and sales in the area in 1951 were 13 percent above 1950. Districts 4 and 5 reported relatively small proportions of the LP-gas sales in 1951, with increases of 24 and 32 percent, respectively, over the 1950 demand.

Over half of the LP-gases were sold for domestic and commercial fuel, and this use increased by 7 percent in 1951 over 1950, compared with a 24-percent gain in 1950 over 1949. This indicated lower rate of growth in the domestic market in 1951 was largely due to the fact that sales reports were received for 1951 from a far greater number of dealers throughout the country, who were in closer contact than producers and wholesalers with small consumers, especially those on farms, and therefore were in a better position to "break out" the proportion of deliveries used for fuel in tractors and other farm equipment and to enter such quantities under "internal-combustion-engine fuel." The result of this more detailed reporting of sales as to end-use was to divert quantities, which in prior years had been included under domestic consumption, to the "internal-combustion-engine fuel" total.

The fast-growing chemical manufacturing industry bought 35 percent more LP-gases for use as raw material and solvents in 1951 than in 1950, and the quantity credited to these plants represented 20 percent of the LP-gas market compared with an 18-percent proportion in 1950. The effort of the Government to stockpile rubber in anticipation of any interruption in international trade was reflected in the large gain—64 percent—in sales of LP-gases for synthetic-rubber components in 1951. LP-gases delivered to synthetic-rubber plants accounted for 9 percent of all sales in 1951 and 7 percent in 1950.

The volume of LP-gases reported as sold for internal-combustion-engine fuel more than doubled in 1951 compared with 1950 and totaled about 7 percent of all requirements compared with a 4 percent share in 1950. The unusual gain in this use in 1951 was due partly to more detailed reporting by a greater number of dealers; but it also resulted from the fact that the "item" for reporting internal-combustion-engine fuel was more clearly defined in the 1951 schedule, by adding that quantities sold for trucks, buses, tractors, pumping equipment, etc., should be included. It is believed that at least part of such sales, especially quantities used in farm equipment, were entered under the "domestic" classification in previous years. The change in the wording in the 1951 schedule also evidently diverted LP-gases consumed as fuel in the petroleum industry which were formerly included under "industrial uses" to "internal-combustion-engine fuel."

Manufactured-gas companies bought 12 percent more LP-gases in 1951 than in 1950 to use for standby purposes, for enriching their manufactured gas, and for direct distribution through their mains to consumers. The quantity required by the manufactured-gas industry was about 7 percent of the LP-gas demand in both 1950 and 1951.

The American Gas Association reported that an average of 309,300 customers, of which 283,300 were residential, received liquefied petroleum gas from utilities during 1951.

Distributors reported a 21-percent gain in sales of LP-gases to industrial plants for fuel and other uses in 1951 compared to a 34-

Digitized by Google

percent rise in this demand in 1950 over 1949. It is believed that some quantities used by petroleum companies in their internal-combustion-engine equipment were formerly included under "industrial uses," which reporting overstated the latter item.

STOCKS

Total stocks of natural-gas liquids at plants and terminals and at refineries increased in 1951 from 7,355 thousand barrels to 8,186 thousand. Stocks of natural gasoline increased 722 thousand barrels, most of the rise taking place at refineries. LP-gas stocks remained substantially unchanged at plants and terminals and declined 153 thousand barrels at refineries. Stocks of "other products" increased at plants and terminals and remained virtually unchanged at refineries.

PRICES

The average price of grade 26–70 natural gasoline to blenders, f. o. b. group 3 (Oklahoma), was 6.18 cents per gallon in 1951, 0.62 cent per gallon above the 1950 average. The increase in the 1951 average over 1950 was due to the fact that prices, after rising during the last 9 months of 1950, held steady during 1951 (except for the normal seasonal weakening during the summer months) at the high level attained by the end of 1950. The average price in January 1951 was 6.88 cents per gallon. It dropped to 5.50 cents from May through August and returned to 6.88 cents in November.

The average refinery price of Regular grade (80 octane) gasoline f. o. b. Oklahoma (group 3) in 1951 was 10.49 cents per gallon, 0.37 cent above the 1950 average. The price was steady at 10.50 cents per gallon through most of 1951, with slight weakening in November and December.

Digitized by Google

The price of commercial propane f. o. b. refineries at New York Harbor held steady at 7.00 cents per gallon in 1951 from January 21 to December 12. The January average price was 7.64 cents. A price rise in December raised the average for that month to 7.16 cents. The average price for 1951 was 7.07 cents per gallon. Due to the rise in prices during the last 9 months of 1950 and the maintenance of these prices in 1951, the 1951 average was 0.73 cent per gallon above 1950.

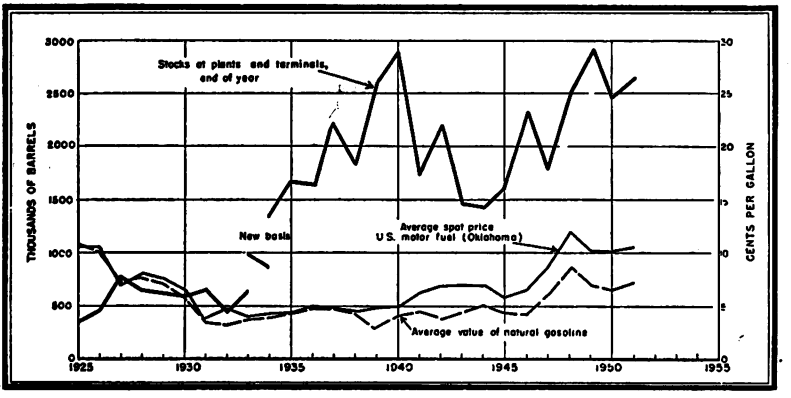

FIGURE 2.—Average value of natural gasoline, spot price of gasoline, and stocks of natural gasoline, 1925–51.

TECHNOLOGY

A plant was placed in operation by the Tennessee Gas Transmission Co. in 1951 for extracting natural-gas liquids from the gas transported through its high-pressure transmission line. This gas had previously been treated in the field to remove enough condensables to make it suitable for pipeline transmission. The plant, by using a refrigeration process that cools the gas stream to −96° F., removes about 15 percent of the ethane and most of the heavier hydrocarbons from the gas stream. The primary purpose of the plant was to recover light hydrocarbons for use in the manufacture of chemicals. By constructing the plant along the pipeline close to the marketing area for the finished products, advantage was taken of the low cost of pipeline transportation.

The first adoption to natural-gasoline-plant use of the deethanizing absorber or rectified absorber was made in 1951 at the Snyder, Tex., plant operated by Sunray Oil Corp. The richness of the inlet-gas stream to this plant made practical use of this type of equipment, heretofore employed only in refineries. A deethanizing absorber produces in one column a deethanized rich oil that requires no further processing, except removal of the absorbed liquids. Lean oil enters the top of the column and contacts the feed gas stream entering midway up the column. The rich oil passing to the lower section of the column is stripped of ethane by vapors produced by a reboiler at the bottom of the column.

FOREIGN TRADE [3]

Exports of LP-gases [4] in 1951 (2,077 thousand barrels) represented a 29-percent gain in the volume of this foreign trade. The value of these shipments increased from $5,748,000 or 8.5 cents a gallon in 1950 to $7,820,000 or 9 cents a gallon in 1951. As in previous years, Canada and Mexico continued to be the most important buyers of LP-gases.

Exports of natural gasoline rose in 1951 mainly because of the sizable shipments made to Australia. Shipments totaled 1,641 thousand barrels, of which 715 thousand went to Canada, 711 thousand to Australia, and 102 thousand to the Netherlands Antilles. The total value of natural gasoline exported in 1951 was $6,963,807 or 10.1 cents per gallon.

Nickel

By Hubert W. Davis

GENERAL SUMMARY

ALLOCATION, prohibition or restriction on use in all nonessential items, inadequate supplies, higher prices, smaller consumption in the United States, and an increase in output in Canada were important features of the nickel situation in 1951.

Despite the fact that the supply of new nickel for the United States in 1951 was 2 percent larger than in 1950, it was inadequate for industry requirements and stockpile commitments. Consequently, consumption and procurement of nickel were subject to NPA Order M–14, effective January 1, 1951, and effective August 15 nickel was placed under complete allocation under Order M–80. Total reported consumption of nickel in the United States in 1951 was 13 percent less than in 1950, which, however, was a peacetime record. Deliveries of nickel to the National Stockpile increased. Stocks of nickel held by consumers in the United States declined 5 percent.

Output of nickel in Canada in 1951 was 11 percent greater than in 1950. In July 1951 the International Nickel Co. of Canada, Ltd., announced that it had achieved its objective of increasing refined-nickel production by 1,000,000 pounds a month. This expansion was completed about 5 months ahead of the target date. Falconbridge Nickel Mines, Ltd., continued its expansion and modernization program. Production of nickel ore in New Caledonia was the largest since 1942 and 60 percent greater than in 1950, but the combined output of matte and ferronickel declined 23 percent. The Government-owned nickel facilities in Oriente Province, Cuba, were being rehabilitated in 1951, and four furnaces were put into operation on January 31, 1952. Domestic output of nickel was, as heretofore, small in 1951. Imports of nickel from Canada were 1 percent greater than in 1950, but those from Norway were up 33 percent. Receipts of refined nickel from France, however, declined 20 percent.

[1] Excludes "All other manufactures of nickel," weight of which is not recorded; also nickel bars, etc., scrap, and residues.
[2] Revised figure.
[3] Excludes "Manufactures," weight of which is not recorded.
[4] Price quoted to United States buyers by International Nickel Co., Inc., for electrolytic nickel in carlots f.o.b. Port Colborne, Ontario; price includes duty of 2½ cents a pound in 1947 and 1¼ cents, 1948–51.

Digitized by Google

The steel industry continued to be the chief consumer of nickel in the United States; 44 percent of all nickel used in 1951 was in stainless and other steels. Consumption in stainless steel was 4 percent larger but that for other steels was 8 percent less. Utilization of nickel in high-temperature and electrical-resistance alloys was up 30 percent, but use for anodes, nonferrous alloys, and cast irons declined 66, 6, and 24 percent, respectively. Most of the nickel consumed in 1951 was in the form of metal, but the proportion of oxide and oxide sinter used was appreciably less in 1951 than in 1950.

Effective June 1, 1951, the contract price to United States buyers for electrolytic nickel in carlots, f. o. b. Port Colborne, Ontario, was advanced to 56½ cents a pound, including duty of 1¼ cents a pound, and for nickel oxide sinter (on which there is no duty) was increased to 52¾ cents a pound (nickel content) f. o. b. Copper Cliff, Ontario. The former prices (50½ and 46¾ cents, respectively) had been in effect since December 13, 1950.

The Geological Survey published a report on the Cle Elum River nickeliferous iron deposits in Washington.[1] According to this report:

> Drilling shows a reserve of 6,250,000 tons of ferruginous material containing 40.86 percent Fe, 0.84 percent Ni, and 2.40 percent Cr_2O_3, underlain by serpentine containing 0.63 percent Ni to an average depth of 21 feet. The iron deposits are subdivided into 3,200,000 tons of measured material, 650,000 tons of indicated material, and 2,400,000 tons of inferred material. The better grades of material generally are in the lower 60 percent of the iron deposits. Much of the material could be recovered only by underground mining, although as much as 1,000,000 tons might be removed by open-pit methods.

The M. A. Hanna Co. began an exploration of the nickel deposit at Riddle in Douglas County, Oreg., during August.

Allocation of nickel metal, oxide, and salts to the free-world countries in the fourth quarter 1951 was announced on October 11 by the International Materials Conference. The United States was allocated 19,690 metric tons, or 63 percent of the total.

PRODUCTION

Domestic production of nickel (other than from imported matte and oxide) is small and comprises metal recovered from scrap (nickel anodes and nickel-silver and copper-nickel alloys, including Monel metal) and primary nickel recovered in copper mining. There has been no output of nickel from ore or as a byproduct of talc production since 1945.

A total of 1,513,000 pounds of nickel, in the form of both crude and refined nickel sulfate, was recovered as a byproduct of copper refining at Baltimore, Md.; Carteret and Perth Amboy, N. J.; Laurel Hill, N. Y.; and Tacoma, Wash. Shipments were 1,551,000 pounds, the bulk of which was crude nickel sulfate sold to refiners for use as an

Digitized by Google

intermediate in the manufacture of refined nickel salts. Although all the nickel recovered as a byproduct of copper refining is credited to domestic production, some is actually recovered from imported blister copper.

In addition to the nickel recovered as a byproduct of copper refining in 1951, 3,443,000 pounds (nickel content) of refined nickel salt (chiefly sulfate) was produced in the United States from domestic crude nickel sulfate and from nickel shot and nickel scrap.

The total production of refined nickel salts in the United States was 3,946,000 pounds (nickel content) in 1951; shipments to consumers for electroplating, catalysts, and ceramics totaled 3,935,000 pounds.

TABLE 2.—Nickel produced in the United States, 1947–51

Year	Primary (short tons) [1]	Secondary	
		Short tons	Value
1947	646	9,541	$7,188,189
1948	883	8,850	6,966,720
1949	790	5,680	4,877,984
1950	913	8,795	8,408,020
1951	756	8,602	9,252,311

[1] Byproduct of copper refining. Value withheld to avoid disclosing individual company operations.

CONSUMPTION AND CONSUMERS' STOCKS

Tables 3 and 4 give data on consumption and consumers' stocks of nickel, as determined by a Bureau of Mines survey. The data cover all known consumers of nickel in the form of new metal, oxide, and matte. The figures for nickel salts, however, fall short of the total and probably represent only 52 and 59 percent of the total in 1951 and 1950, respectively.

TABLE 3.—Nickel (exclusive of scrap) consumed and in stock in the United States, 1950–51, by forms, in pounds of nickel

Form	1950			1951		
	Consumption	Stocks at consumers' plants Dec. 31	In transit to consumers' plants Dec. 31	Consumption	Stocks at consumers' plants Dec. 31	In transit to consumers' plants Dec. 31

[1] Comprises copper-nickel alloys, nickel-silver, brass, bronze, beryllium alloys, magnesium and aluminum alloys, Monel, Inconel, and malleable nickel.
[2] Figures for solutions for 1947, 1948, 1949, 1950, and 1951 represent about 25, 40, 50, 55, and 48 percent, respectively, of total.
[3] Figures for catalysts for 1947, 1948, 1949, and 1950 represent about 37, 37, 42, and 84 percent, respectively, of total.
[4] Figures for ceramics for 1947–50 represent about 50 percent of total.

FOREIGN TRADE [2]

The quantity of new nickel imported into the United States in 1951 was 2 percent more than in 1950. Imports comprised chiefly metal, oxide, and matte. As heretofore, Canada was the chief source of the imports. At the plant of the International Nickel Co., Inc., Huntington, W. Va., the roasted and sintered matte was refined to Monel metal and other products.

TABLE 5.—Nickel products imported for consumption in the United States in 1951, by countries, gross weight in pounds [1]

[U. S. Department of Commerce]

Union of South Africa					35,840		
United Kingdom	143,410			11,334	762,855		
Total	153,360,302	25,657,660	23,972,578	75,054	1,581,742	3,491	564,246

[1] In the corresponding table in Minerals Yearbook, 1950, imports of metal from Belgium-Luxembourg should read 135,581 pounds and total metal 138,397,272 pounds (revised figures).
[2] Separation of metal from scrap is on basis of unpublished tabulations.
[3] Contains 10–30 percent nickel; balance mostly copper.
[4] Reported to Bureau of Mines by importers.
[5] According to reports by importers to the Bureau of Mines, the roasted and sintered matte averages about 68.5 percent nickel, the oxide and oxide sinter about 75 percent, and the nickel residues about 29 percent nickel.

[2] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Digitized by Google

The nickel content of refined metal, matte, oxide, and residues imported into the United States is estimated at 186,231,000 pounds in 1951, compared with 182,562,000 pounds (revised figure) in 1950 and 182,146,000 pounds (revised figure) in 1949.

Since January 1, 1948, the rate of duty on refined nickel imported into the United States has been 1¼ cents a pound. Nickel ore, matte, and oxide enter the United States duty free.

Exports of nickel comprise largely products manufactured from imported raw materials. Exports of alloy and scrap in 1951 were 41 percent over 1950; but those of metal, nickel-chrome electric-resistance wire, and nickel-silver were smaller by 43, 8, and 11 percent, respectively.

The United Kingdom (4,821,471 pounds), Canada (2,247,391 pounds), Japan (577,575 pounds), Germany (201,342 pounds), and Netherlands (183,149 pounds) were the chief foreign markets for nickel, Monel metal, alloys, and scrap in 1951.

WORLD REVIEW

Table 8 shows world production of nickel by countries, 1944–51, insofar as statistics are available. Despite the fact that nickel is produced in many countries, one country—Canada—has supplied about 77 percent of the world output since 1944.

TABLE 8.—World mine production of nickel, 1944–51, by countries, in metric tons of contained metal

[Compiled by Berenice B. Mitchell]

[2] Revised figure.
[3] Preliminary data for year ended Mar. 31 of year following that stated.
[4] Less than 0.5 ton.
[5] Estimate.
[6] Byproduct in electrolytic refining of copper. In 1944 and 1945 includes also production from ore.

Canada.—Virtually all the Canadian output is derived from copper-nickel ores of the Sudbury district, Ontario. Some nickel is also recovered as a byproduct from silver-cobalt ores of Cobalt, Ontario. Two companies—International Nickel Co. of Canada, Ltd., and Falconbridge Nickel Mines, Ltd.—are the principal producers. Nickel production in Canada was 137,268 short tons in 1951 compared with 123,659 tons in 1950. Exports of nickel from Canada were 130,239 short tons in 1951 compared with 119,984 tons in 1950.

Sales of nickel in all forms by the International Nickel Co. of Canada, Ltd., were 243,865,030 pounds in 1951 compared with 256,410,543 pounds in 1950.[3] Sales in 1950 included withdrawals from stocks of refined nickel accumulated from operations in 1949, when demand was slack and governments were limiting their purchases for stockpiling.

During 1951 underground mining was increased substantially beyond that achieved in any previous year. Underground ore mined was 7,780,143 short tons compared with 5,733,269 tons in 1950 and 5,015,318 tons in 1949, reflecting the rapid progress in the program of conversion to exclusively underground mining. Open-pit ore mined was 4,019,177 tons compared with 4,115,755 tons in 1950 and 4,969,573 tons in 1949. Accordingly, total ore mined was 11,799,320 tons in 1951 compared with 9,849,024 tons in 1950 and 9,984,891 tons in 1949. According to the company, proved ore reserves at the end

[3] International Nickel Co. of Canada, Ltd., Annual Report: 1951, 28 pp.

Digitized by Google

of 1951 were 253,705,000 short tons containing 7,693,000 tons of nickel-copper compared with 252,860,000 tons containing 7,669,000 tons of nickel-copper at the end of 1950. Underground development in the producing mines advanced 89,269 feet (17 miles) in 1951, bringing the total footage to 1,585,546 or over 300 miles.

Concerning developments and exploration in 1951 the company reported as follows: [4]

Mining of the Stobie open pit was completed early in August to the depth planned. The Frood open pit was continued in production throughout the year at a rate calculated to preserve a flow of ore from this source until the expanded underground mining facilities which we have under construction are ready to be operated at full capacity.

All three of the new major mining operations involved in our program to replace the open pit ores, namely, the Creighton project for mining lower-grade ores by low-cost caving methods, the mining of the Stobie section of the Frood-Stobie Mine, and the Murray Mine project, produced ore from regular operations during the year.

The new No. 7 Creighton shaft, the related underground ore bins and crusher station, the permanent hoist house on the surface, the new crushing plant and concentrator, and the pipe lines for transporting the bulk concentrate 7½ miles to Copper Cliff, were all completed during the year. Regular production from the first area of the Creighton caving project was delivered through this new shaft in July, in time to replace the tonnage which theretofore had been obtained from the Stobie open pit. By the year-end the daily mine rate had been lifted to 10,000 tons of ore from the caving area and operations in the new crushing plant and concentrator had been brought to full scale and integrated into the milling operations at Copper Cliff.

Additional areas are being developed in the Creighton caving area to bring this mine project to a condition of stabilized production. Ore-passes and slusher-ways are being advanced to serve the extension of caving area and work is also progressing on the elaborate ventilation system required to maintain satisfactory working conditions. A second underground crusher installation is under way to handle ore from the new caving areas. Plans have now been completed further to increase the daily capacity of the new concentrator by 2,000 tons, bringing the daily capacity to 12,000 tons.

At the Stobie section of the Frood-Stobie Mine we commenced ore shipments to the concentrator at Copper Cliff at a daily rate of 3,000 tons. The large underground crusher installations at the 600- and 1,000-foot levels, along with the necessary ore-passes, were completed and put into operation. Preparation of stopes is under way to bring the area served by these installations into regular ore production as soon as possible. Preliminary work is in progress also on the 1,400 foot level crusher and ore-pass system.

Work continued on the sinking and equipping of the new No. 8 shaft at Stobie required to provide additional ore hoisting capacity and flexibility in the Stobie phase of the conversion program.

At the Frood section of the Frood-Stobie Mine alterations were completed, increasing the ore handling capacity of the main Frood shaft and improving the operating efficiency of the No. 3 rock house.

Production from the Murray Mine, which had been put on a regular production basis of 4,500 tons daily at the start of the year, was increased to 5,000 tons daily. More stoping area is being developed to meet the requirements of the complete conversion program. The deepening of the Murray Mine shaft was completed during the year, making way for the exploring and developing of the lower level ores.

At Levack Mine, work proceeded on the deepening of the existing main shaft and the sinking also of the new internal shaft. The new shaft will allow the exploiting of the lower level ores that are not now accessible. Both of these shaft projects will be completed in 1952.

Large scale development for future mining was continued throughout the year of the deeper levels of the Creighton Mine; at the Frood section of the Frood-Stobie Mine, where the mining, by low-cost blasthole methods, of levels immediately below the open pit reached scheduled production; and at Garson Mine in

[4] Work cited in footnote 3; pp. 8-9, 12.

Digitized by Google

the area of the existing main shaft. The deepening of the Garson main shaft continued on schedule.

The company's program of exploration in search for new sources of nickel for future needs was further expanded during the year. The program has involved continuous geological work on our known deposits, extensive studies of the geology of other parts of the Sudbury Basin and property examinations or prospecting elsewhere in Canada and throughout the world.

The cost of the entire exploration program during the year was $2,593,908 compared with $1,682,436 in 1950 and $1,554,373 in 1949. The number of feet of exploration drilled in Canada was 289,677 compared with 260,127 in 1950 and 149,399 in 1949.

Major exploration camps were operated in Ontario, Manitoba, and the Northwest Territories, and projects were carried on also in Saskatchewan and Quebec. Outside of Canada, exploration was started in Tanganyika and property examinations were made in seven other countries.

Comprehensive exploration to determine the ore possibilities of our Crean Hill Mine also has been proceeding, following the dewatering and shaft reconditioning which was completed in April. This mine was closed as an operating unit in 1919.

The metallurgical plants of Falconbridge Nickel Mines, Ltd., at Falconbridge treated 1,083,670 short tons in 1951, a new record, compared with 928,650 tons in 1950. The new record was achieved by operating the ore-dressing plant 363 days on a two-shift basis and the concentrator and two blast furnaces 99.7 and 99.4 percent, respectively, of the total yearly hours. Production of matte was 17 percent greater than in 1950 and the highest in company history. Ore hoisted at the Falconbridge Mine was 930,164 tons in 1951 (881,838 tons in 1950), and output at the McKim mine was 155,961 tons (46,997 tons in 1950).

Concerning developments at its mines in 1951, the company reports as follows: [5]

Falconbridge Mine.—The exploratory drive at the 2,625 horizon was driven a further 1,242 feet during the year, and four short ore shoots were exposed which will be explored further on one of the deeper levels. The westerly drive on the 2,800 level was advanced 698 feet and confirmed the ore zone mentioned in last year's report. Other major development work included opening up the 2,975 level east and west of No. 5 shaft and driving east on the 3,150 level. These drives showed ore of mine average grade with better than average widths to the east.

Below the 3,150 level, considerable waste rock was carried out from the internal shaft including driving shaft raises for extending the main No. 5 shaft to the 4,200 horizon. On the 3,850 level the orebody was reached and opened up for a length of 129 feet while on the 4,025 level the east and west drifts were extended a total of 1,787 feet. These drives showed ore of average mine width and grade, but unexpected difficulty was experienced on the 4,025 east drift in driving through an area where a low angle shear zone intersects the contact shear zone. This local condition has been overcome in the drift.

Extension of the ore pass system to the 4,025 level was started.

Work on the "Southwall" orebody was confined to 700 feet of drifting on the 2,450 level and diamond drilling on the 2,975 and 4,025 levels. Results on the two upper levels were as expected, but on the 4,025 level drilling to date has indicated several areas of dissemination but only one notable ore shoot. Continuation of deep drilling has confirmed the presence of "Southwall" ore to the 5,700 horizon in the main shaft section but as yet this deep drilling has been confined to the one section, pending the driving of the required hanging wall crosscuts on the 4,025 level.

East Falconbridge Mine.—A new three compartment shaft, No. 8, was collared some 4,500 feet easterly from Falconbridge No. 5 shaft and reached a depth of 245 feet by the year end with one station established. This shaft is being sunk to explore and prepare for mining the eastern section of the property. As part of this program, the 802 drift was extended 2,039 feet east from No. 5 shaft and is now east of No. 8 shaft location. Low grade ore intersections shown by this

[5] Falconbridge Nickel Mines, Ltd., 23d Annual Report: 1951, 24 pp.

Digitized by Google

drive confirm previous diamond drill results from surface. This shaft will ultimately connect with the 1,750 and 2,800 drifts already driven to the eastern property boundary from the main ore zone.

McKim Mine.—Stoping was carried out from three levels with preparation work proceeding on two more levels. Stoping on the upper levels reveals the ore to be much wider than expected, but lower level drifts indicate a narrower and shorter ore body, particularly on the 1,175 and 1,350 levels, the latter being the lowest level presently opened. For the year McKim exceeded its rated production capacity of 500 tons a day, and should do substantially better in 1952. Because of its massive nature and good grade, McKim ore has proven to be a beneficial addition to the Falconbridge blast furnaces.

An exploratory drive was made 1,099 feet east on the 1,350 level along the norite-greenstone contact, but failed to find anything of importance. The west drive on this level was advanced 351 feet, mostly in medium grade ore. On the 1,175 level the west drift was extended 1,101 feet along the ore zone and through the diabase dyke. The ventilation escapement raise was extended to the 1,175 level.

The problem of McKim ore freezing in winter months during its transportation by rail to the Falconbridge smelter has been solved by the construction of a thaw shed.

Hardy Mine.—Shaft sinking was started during February and reached a depth of 1,028 feet at year end. Stations were established at 125 feet intervals from the 250 to 1,000 level, inclusive, and crosscuts commenced on each level. Development of the Hardy Mine will be proceeded with as rapidly as the availability of machinery, equipment, and power permit.

Expansion of the milling and smelting facilities continued throughout 1951, and a further expansion program of these units was under way at the year end.

According to Falconbridge Nickel Mines, Ltd., ore reserves totaled 19,116,500 short tons on December 31, 1951, and comprised 10,102,500 tons of developed ore averaging 1.64 percent nickel and 0.87 percent copper in the Falconbridge and McKim mines and 9,014,000 tons of indicated ore averaging 1.85 percent nickel and 1.14 percent copper in Sudbury-district holdings. A net increase of 3,236,000 tons in indicated ore reserves results from inclusion of an ore body found at depth under Fecunis Lake, some 2½ miles east of the Hardy Mine. Five diamond-drill intersections have been obtained from this deep-ore zone, but the limits of mineralization have not been determined.

The Sherritt Gordon Mines, Ltd., made much progress toward its construction program designed to bring its mines at Lynn Lake into production by the end of 1953. This program involves the development of the "A" and "EL" mines, transplanting the mining plants, concentrator and employees' houses from Sherridon to Lynn Lake, development of hydroelectric power on the Laurie River, extension of the railroad from Sherridon to Lynn Lake, and construction of a chemical metallurgical plant in Alberta.[6] The railroad extension, which is being built by the Canadian National Railways, is reported to be up to schedule.

After a thorough study of various locations in Alberta, Sherritt Gordon Mines, Ltd., has decided to locate its chemical metallurgical plant at Fort Saskatchewan, 15 miles northeast of Edmonton. Fort Saskatchewan is on the Canadian National Railways and has adequate supply of water and natural gas. Work on the design of this plant was in progress in 1951, and construction will start during the second quarter 1952.

The work of deepening the "A" shaft, begun at the end of 1950, continued to June 1951, when the shaft reached a depth of 1,628 feet.

[6] Sherritt Gordon Mines, Ltd., Annual Report: 1951, 16 pp.

Digitized by Google

Lateral development followed on the 14th and 16th levels in preparation for production. The 14th level is to open a scram system underneath the lower "A" ore body. The underground crushing installation will be on the 16th level. No exploratory development was undertaken except some diamond drilling to outline known ore on the new levels so that the drives could be located. The small amount of exploration done confirmed all previous ore indications, and the ore reserve remains at 14,055,000 tons assaying 1.223 percent nickel and 0.618 percent copper. Major permanent construction at the "A" shaft area was begun in 1951. Foundations were completed for the hoist house, main hoist, main substation, powerhouse, shops, and warehouse. Structural steel was erected at the main substation, and three-fifths of the steel work was erected and sheeted at the powerhouse. Excavation work for the ore bins and the crusher house was completed and a start made on the bin foundations. The concentrator area was completely stripped of overburden, and some rock excavation was started. Piers were poured for the fire tower. Foundations were ready for transformers in both the 2,300 and 500 substations; all substation poles were erected, and some of the main distribution poles were placed. A power line was cut from the "A" plant to the townsite and on to the "EL" plant. The right-of-way for the "EL" narrow-gage railway was cleared. In December 1951 the first house was moved from Sherridon to Lynn Lake. At the "EL" mine the former Sherridon East shaft steel headframe was erected. The hoist and powerhouse building was also completed, and the hoist was partly assembled. Foundation work and steel erection were completed for the change house, and sheeting was in progress.

Work on development of hydroelectric power for the permanent Lynn Lake plant was begun in the spring of 1951 on the Laurie River at Mile 18. This site will generate 7,000 horsepower and requires a concrete dam 900 feet long at the top, with an operating head of 55 feet.

During the first part of the year the pilot plant was operated to demonstrate the complete process, treating 600 pounds of nickel concentrate per day. Results of this work, along with improved control features and new techniques developed in the research laboratory, were used as the basis to expand the pilot-plant capacity to 3,000 pounds a day. The leaching section of this enlarged pilot plant was operated for demonstration during December. Subsequent metal reduction and ammonium sulfate-recovery processes were to be demonstrated during the first quarter of 1952. Development work on the acid-oxidation process, which was being demonstrated for Chemical Construction Corp., was carried out intermittently from July to December.

The Sherritt Gordon property at Lynn Lake was described in a trade magazine.[7]

Cuba.—Rehabilitation of the nickel facilities at Nicaro, Cuba, proceeded throughout 1951 and four furnaces were put into operation on January 31, 1952—60 days ahead of schedule. The eight additional

[7] Waldron, H. L., Sherritt Gordon Develops Lynn Lake Nickel-Copper: Eng. and Min. Jour., vol. 152, No. 11, November 1951, pp. 72–78.

Digitized by Google

furnaces were scheduled for reactivation by mid-1952. The Nicaro plant was to have an annual production of 30 million pounds of nickel as oxide. A majority interest in Nickel Processing Corp., operator of the Government-owned nickel plant at Nicaro, was acquired by the National Lead Co. National Lead Co. and Fomento de Minerales Cubanos S. A. purchased N. V. Billiton Maatschappij's interest in the corporation and rights to certain processes which may further expand output of the plant.

Japan.—Some 8,000 tons of nickel ore from New Caledonia arrived in Japan in August 1951. It was destined for treatment at the Saganeseki refinery of the Nippon Mining Co. for ferronickel manufacture.[8]

New Caledonia.—Production of nickel ore in New Caledonia in 1951 was the highest since 1942—252,335 metric tons compared with 157,645 tons in 1950. Production in 1951, by mines, is shown in table 9.

TABLE 9.—Production of nickel ore in New Caledonia in 1951, by mines

Mine	Metric tons	Nickel, percent	Operator
Thio	195,500	3.25	Société le Nickel.
Pin Pin	47,060	5.25	Do.
Tao V	5,001	4.00	M. Henri LaFleur.
Medona	1,974	6.00	Do.
Tunney 10	1,800	2.80	M. Paul Videault.
André	1,000	4.50	Do.

The ore produced at the Tao V and Medona mines was processed to matte at the Doniambo plant of Société le Nickel for export to France to customers other than those of Société le Nickel. The ore produced at the Tunney 10 and André mines was for export to Japan.

Production of nickel matte and ferronickel by Société le Nickel declined substantially in 1951 from 1950, mainly because of delay in delivery of Australian coal. During the last several months of 1951 operations were disrupted by the necessary dismantling of one of the two water-jacket furnaces for rebricking, at which time one of the two operating electric furnaces exploded, putting all electric furnaces out of operation.

TABLE 10.—Production of nickel matte and ferronickel by Société le Nickel in 1950 and 1951, in metric tons

Product	1950		1951	
	Gross weight	Nickel content	Gross weight	Nickel content
Matte	6,290	4,859	3,614	2,796
Ferronickel (electric furnace)	4,192	1,450	2,547	856
Ferronickel (water-jacket furnace)			1,885	602
	10,482	6,309	8,046	4,254

[8] Metal Bulletin (London), No. 3638, Oct. 30, 1951, p. 17.

Digitized by Google

Exports of nickel by Société le Nickel comprised 4,142 metric tons of matte containing 3,287 tons of nickel and 3,694 tons of ferronickel containing 1,222 tons of nickel in 1951 compared with 5,790 tons of matte containing 4,480 tons of nickel and 1,118 tons of ferronickel containing 440 tons of nickel in 1950.

Norway.—Production of refined nickel and copper at the refinery of Falconbridge Nickel Mines, Ltd., at Kristiansand in 1951 was the highest in company history.[9] By year end, construction work of the new plant facilities was practically completed for an annual capacity of 30 million pounds of nickel, and the new equipment was being tested before the process change scheduled for the first quarter of 1952. Present plans include a further increase in refining capacity to a minimum of 35,000,000 pounds of nickel per year. This can be accomplished by extension of the tank houses and other relatively minor changes. Production of nickel sulfate from the newly installed facilities was continuous during the latter part of 1951, although at a rate less than anticipated capacity. The new roaster and anode furnace unit was placed in operation early in 1951 and performed satisfactorily.

United Kingdom.—The nickel refinery of Mond Nickel Co. at Clydach, Wales, was operated at maximum capacity in 1951 and output of nickel was the highest on record.

Nitrogen Compounds

By E. Robert Ruhlman

GENERAL SUMMARY

DURING 1951, nitrogen supplies were less than demand in the United States. Increased agricultural requirements and the rearmament program utilized all the nitrogenous material that industry was capable of producing. The shortage of nitrogenous materials and estimated future government requirements were causing the nitrogen industry in the United States to plan substantial expansion.

Ammonium nitrate exports were controlled throughout 1951 by the Office of International Trade, and after November 20 exports of all fertilizer nitrogen materials required export licenses.

Ammonia solutions, ammonium sulfate, ammonium nitrate, and synthetic sodium nitrate continued to be the principal nitrogen compounds produced domestically. Imports of fertilizer nitrogen materials increased in 1951, but exports of both industrial and fertilizer nitrogen were lower than in 1950.

DOMESTIC PRODUCTION

Ammonium Compounds.—Domestic production of synthetic anhydrous ammonia in 1951 (1,767,000 short tons) was 13 percent more than in 1950 and broke all previous records. The only anhydrous ammonia plant still in the Army's possession—The Morgantown Ordnance Works, Morgantown, W. Va.—was leased to the Mathieson Chemical Corp.

Total production of ammonium sulfate in 1951 decreased over 23 percent, with synthetic plants producing only 622,000 short tons compared to 1,138,000 tons in 1950. This decrease reflected cessation of the Army's purchasing program to supply fertilizer nitrogen to Germany, Japan, and Korea. The sulfur shortage contributed to the smaller supply of ammonium sulfate. Byproduct coking plants increased their production 8 percent to 898,000 tons in 1951 compared to 831,000 tons in 1950.

Ammonium nitrate production reached another alltime high in in 1951—1,346,000 tons. As usual, agriculture consumed the largest proportion of ammonium nitrate.

The Daniels process for direct oxidation of atmospheric nitrogen to produce nitric oxide reached the production stage after several years of research by Wisconsin Alumni Research Foundation and

Digitized by Google

Food Machinery & Chemical Corp. A large plant utilizing this process was being constructed at the Sunflower Ordnance Works, De Soto, Kans.

The numerous companies announcing expansion programs in 1951 included the Solvay Process Division, Allied Chemical & Dye Corp., at its Hopewell, Va., and South Point, Ohio, plants, with a combined expansion of 100,000 tons of nitrogen annually, using natural gas in place of coke as the source of hydrogen. Other companies announcing expansion programs or construction of new plants were: Commercial Solvents Corp., Sterlington, La.; Consumers Cooperative Association, Lawrence, Kans.; Illinois Anhydrous Ammonia Co., Farmer City, Ill.; Mississippi Chemical Corp., Yazoo City, Miss.; Shell Chemical Corp., Pittsburg, Calif.; and the Spencer Chemical Co., Jayhawk Works, Pittsburg, Kans., and Vicksburg, La.

TABLE 1.—Principal nitrogen compounds produced in the United States, 1948–51, in short tons

Commodity	1948	1949	1950	1951
Ammonia (NH_3):				
Synthetic plants: Anhydrous ammonia [1]	1,089,786	1,294,057	1,565,569	1,767,043
Byproduct coking plants (NH_3 content):				
Aqua ammonia	24,753	22,750	23,387	24,878
Ammonium sulfate	207,671	189,202	207,754	224,566
Subtotal	232,424	211,952	231,141	249,444
Grand total	1,322,210	1,506,009	1,796,710	2,016,487
Principal ammonium compounds:				
Ammonium sulfate:				
Synthetic plants [1]	264,476	846,195	1,137,721	622,084
Byproduct coking plants [2]	830,683	756,807	831,016	898,263
Total	1,095,159	1,603,002	1,968,737	1,520,347
Ammonium nitrate, basis solution, 100 percent NH_4NO_3 [1]	988,342	1,018,706	1,213,911	1,346,443

[1] Data from Bureau of Census Monthly Facts for Industry series.
[2] Does not include ammonium sulfate produced at byproduct coking plants from purchased anhydrous ammonia as follows: 1948—30,749 short tons; 1949—58,826 short tons; 1950—14,699 short tons; and 1951—none.

The Missouri Ordnance Works at Louisiana, Mo., operated during World War II by the Army to produce synthetic ammonia and since the end of the war by the Bureau of Mines as a demonstration synthetic liquid fuels plant, was transferred to the Bureau of Mines in 1951.

Sodium Nitrate.—The synthetic nitrate of soda consumed in the United States in 1951 was produced domestically; none was imported. Only two companies were in production—Solvay Process Division, Allied Chemical & Dye Corp., Hopewell, Va., and Mathieson Chemical Corp., Lake Charles, La.

CONSUMPTION AND USES

As in the past, the major part of the nitrogen supply was consumed by agriculture, with smaller quantities used by industry. A small quantity of elemental nitrogen is used for industrial purposes, but most nitrogen enters both agriculture and industry in various chemical

Digitized by Google

compounds. According to the United States Department of Agriculture more than 1.2 million short tons of nitrogen was consumed by agriculture during the fiscal year ended June 30, 1951. The principal chemical nitrogen materials, in order of importance, were (1) ammonium nitrate and ammonium nitrate-limestone mixtures, (2) sodium nitrate, (3) ammonium sulfate, (4) anhydrous ammonium and solutions, (5) calcium cyanamide, and (6) calcium nitrate.

According to the United States Department of Agriculture, consumption of ammonium nitrate in the year ended June 30, 1951, was 638,176 tons, a 10-percent increase over the preceding 12 months. Consumption of other fertilizer nitrogen materials increased as follows: Ammonium sulfate, 97 percent; ammonium nitrate-limestone mixtures, 87 percent; and sodium nitrate, 9 percent. Demand for anhydrous ammonia continued to grow during the year, with over 118,000 tons reported consumed.

PRICES

Prices for nitrogen compounds were frozen on January 26 by GCPR (General Ceiling Price Regulation) at the highest price charged during the base period of December 19, 1950–January 25, 1951. The manufacturers' regulation (CPR 22) issued April 25, 1951, permitted minor price adjustments to correct inequalities caused by GCPR if so desired by the manufacturer. Numerous supplementary regulations and amendments were issued during the year, permitting price increases. The prices for various nitrogen compounds in effect at the opening, middle and end of 1951, as quoted in the Oil, Paint and Drug Reporter, are shown in table 2.

TABLE 2.—Prices of major nitrogen compounds in 1951, per short ton [1]

Commodity	Jan. 1, 1951	July 9, 1951	Dec. 31, 1951
Chilean nitrate, port warehouse, bulk	$48.00	$50.00	$53.50
Sodium nitrate, synthetic domestic, c. i. works, crude, bulk	45.00	45.00	47.50
Ammonium sulfate, coke ovens, bulk	32.00–45.00	40.00–45.00	40.00–45.00
Cyanamide, fertilizer-mixing grade, 20% N, granular, Niagara Falls, Ont.:			
Bulk	54.00		
Bagged		65.45	65.45
Ammonium nitrate, fertilizer grade:			
Canadian eastern, 32.5% N, c. i., shipping point, bags	69.50	69.50	69.50
Western, domestic, works, bags	61.00–63.00	61.00–63.00	61.00–63.00
Anhydrous ammonia, fertilizer, tanks, works	74.00–80.00	79.00–80.00	79.00–80.00
Ammonium nitrate-dolomite compound, 20.5% N, Hopewell, Va., bags	46.00	48.50	51.00

[1] Quotations from Oil, Paint and Drug Reporter of the dates listed.

FOREIGN TRADE [1]

As in previous years, imports of natural Chilean nitrate greatly exceeded the imports of any other nitrogenous material. The tonnage of Chilean sodium nitrate imported increased more than 17 percent compared with 1950, to 725,800 tons, the highest since 1945. The value of these imports rose in 1951 to $27,016,000.

Chilean potassium-sodium nitrate imports dropped to 5,566 tons valued at $244,300.

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

WORLD REVIEW

World demand for nitrogen continued to increase during 1951, resulting in new records in both production and consumption. Although

Digitized by Google

estimates of production and consumption by the United Nations Food and Agriculture Organization and by Aikman (London), Ltd., differ, they both show an apparent production surplus for 1951–52. According to the Aikman Co., for the period July 1, 1949, through June 30, 1952, there was an apparent surplus of over 650,000 metric tons of nitrogen for agriculture. Details of world production and consumption are shown in tables 5 and 6.

Expansion of world nitrogen facilities was taking place rapidly because of the increased demand throughout the world for more fertilizers. A new plant was being constructed at Oulu, Finland, to produce about 16,000 metric tons of fertilizer nitrogen compounds annually. Bamag-Meguin of Germany developed a new process for the manufacture of nitric acid reported to be of lower unit cost than other methods.[2] Other new plants for various nitrogen compounds were either being constructed or planned in Brazil, Canada, Colombia, Egypt, Iceland, India, Spain, Sweden and many other countries.

The Anglo Chilean Nitrate Corp. and Lautaro Nitrate Co., Ltd., representing a large share of the nitrate industry in Chile, completed plans to merge under the new name of Anglo Lautaro Nitrate Co.

TABLE 5.—World production and consumption of fertilizer nitrogen compounds, fiscal years ended June 30, 1950–52, by principal country, in metric tons of contained nitrogen

[United Nations Food and Agriculture Organization]

Peat

By J. A. Corgan and Golden V. Chiriaco

GENERAL SUMMARY

PRODUCTION of peat in the United States in 1951 increased about 49 percent in tonnage and 30 percent in value over 1950. The output is used entirely within the United States, none being exported. Imports increased about 16 percent over 1950 and accounted for about 43 percent of the 338,947 tons consumed in this country in 1951.

TABLE 1.—Salient statistics of the peat industry in the United States, 1947–51

	1947	1948	1949	1950	1951

[1] Revised figure.

RESERVES

There were no new developments during 1951 with regard to reserves of peat which remained at slightly less than 13,827,000,000 short tons (*see* Peat Chapter, Minerals Yearbook, 1950, p. 869).

PRODUCTION

Sixty-three producers operating in 17 States contributed to the 1951 production of 194,416 short tons of peat reported to the Bureau of Mines, as compared with 48 producers operating in 17 States in 1950. Although the industry in general showed a substantial increase over 1950, part of the rise in production in 1951 can be attributed to the output of a number of operations reporting to the Bureau for the first time. The total value of peat produced in 1951, $1,489,225, represents a 30-percent increase over the 1950 value of $1,142,566, whereas the average value per ton in 1951, $7.66, was a decrease of 12.4 percent from the 1950 value of $8.74. The overall decline in the average per-ton value and, particularly, the sharp decline in the average value in moss peat can be attributed principally to the low value reported by several large producers of moss peat.

More peat was produced in Washington in 1951 than in any other State. The output of Washington together with that of the next three leading States—New Jersey, Florida, and Ohio—accounted for

Digitized by Google

about 62 percent of the United States total. Other producing States, in order of output, were Michigan, Iowa, Pennsylvania, California, Indiana, Connecticut, Illinois, Georgia, Colorado, Maine, Texas, Wisconsin, and Massachusetts.

Peat humus, produced in 14 States in 1951, constituted about 64 percent of total peat production; reed, or sedge, produced in 8 States, about 24 percent; and moss peat and other, produced in 9 States, about 12 percent.

[2] Reported under "Moss peat" to avoid disclosure of individual company operations.

USES

For many years peat has been used in this country primarily for soil improvement. Of the total sales reported for 1951 about 73 percent was so used, about 19 percent was sold for mixed fertilizers, and about 8 percent was consumed in other uses.

United States Government Specifications.—The Federal Government purchases a certain amount of peat, principally for horticultural purposes, provided the peat meets required specifications. These specifications may be obtained from the Federal Supply Service, General Services Administration, Washington 25, D. C.

IMPORTS [2]

The quantity of moss peat imported into the United States in 1951 reached an alltime high of 144,531 short tons, an increase of 16 percent over the 124,382 tons (revised figure) imported in 1950 and about 84 percent over the 1939 prewar figure of 78,611 tons. In 1951, as in past years, no exports of peat were reported.

WORLD PRODUCTION

As indicated in table 6, the estimated world production of peat in 1951 increased slightly over 1950. Because of the lack of specific data, it has been necessary to estimate production in many countries from the most reliable information available.

TABLE 6.—World production of peat, 1946–51, by countries, in metric tons

By A. G. White, A. T. Coumbe, and A. L. Clapp

GENERAL SUMMARY

THE SHUTDOWN of the Abadan refinery in Iran during the last half of 1951 had a major effect on oil operations and total oil demand in the United States.[1]

The volume of crude oil refined in Iran averaged only 272,000 barrels daily in 1951, compared with 524,000 barrels daily in 1950. Runs to stills in the first half of 1951 averaged 507,000 barrels daily compared with 43,000 barrels daily in the last half. Although this loss in refinery output was more than offset by the rise in total crude runs in Western Europe (1,100,000 barrels daily in 1951 compared with 793,000 barrels daily in 1950), the situation outside the United States changed abruptly from an expectation of ample supplies of crude petroleum and products to one of shortages in meeting the large increase in demand abroad.

The most direct effect in the United States was an increase in the exports of refined products to 126 million barrels, a gain of 49 million compared with 1950, when a further decline might have been expected. Exports of refined products by quarters in 1951, compared with 1950, gained 3 percent in the first quarter, 55 percent in the second, 126 percent in the third, and 66 percent in the fourth. Part of the increase of 13 million barrels in the amount of heavy fuel oil used to bunker ships engaged in the foreign trade in 1951 can be attributed to the shortage in supplies abroad. These figures seem to warrant a rough estimate that the total demand for all oils in the United States was increased by about 2 percent above normal expectations in 1951. Furthermore, the gain of only 1 percent in crude-oil imports and the decline of 3 percent in the imports of refined products in 1951 can be attributed to this situation.

The total demand for all oils in the United States amounted to 2,726 million barrels in 1951, including total exports and shipments to Territories of about 155 million barrels and a domestic demand of 2,571 million in continental United States. Compared with 1950, total demand increased 9.6 percent, exports were 39 percent higher, and domestic demand was 8.3 percent greater.

Exports of refined products increased 65 percent, whereas crude exports declined 18 percent. The decline in crude exports was due

[1] Certain terms, as utilized in this chapter, are more or less unique to the petroleum industry. Principal terms, and their meaning, are as follows:

Total demand.—A derived figure representing total new supply plus decreases or minus increases in reported stocks. Because there are substantial secondary and consumers' stocks that are not reported to the Bureau of Mines, this figure varies considerably from consumption.

Domestic demand.—Total demand less exports.

New supply of all oils.—The sum of crude-oil production, plus production of natural-gas liquids, plus benzol (coke-oven) used for motor fuel, plus imports of crude oil and petroleum products.

Transfers.—Crude oil conveyed to fuel-oil stocks without processing or reclassification of products from one product category to another.

All oils.—Crude petroleum, natural-gas liquids, and their derivatives.

Principal products.—Gasoline, kerosine, distillate fuel oil, and residual fuel oil.

302512—54——60

Digitized by Google

primarily to the increased deliveries of Canadian crude oil via pipeline to Lake Superior and Lake tankers to refineries in Ontario.

Domestic demand includes all oil delivered to the Armed Forces in the United States, both for use at home and for shipment abroad in military custody. Data collected by the Bureau of Mines show a gain of 25 million barrels in the military deliveries of distillate fuel, residual fuel, and aviation gasoline in 1951 as compared to 1950. Of the total gain of 8.3 percent in domestic demand, less than 7 percent, represents the increase in civilian demand after all military deliveries were deducted.

The new supply of all oils (production plus imports) gained about 12 percent in 1951 compared with 1950. The larger relative gain in supply, as compared with total demand, resulted from the addition of over 32 million barrels to total stocks in 1951, whereas total stocks were reduced by 20 million barrels in 1950. The increase of 24 million barrels in stocks of refined products compared with the decline of 16 million barrels in 1950 was an important factor in the gain of over 13 percent in total crude runs in 1951. The principal changes in total stocks in 1951 were gains of 7.3 million barrels in crude-oil stocks, 0.8 million in natural-gas liquids stocks, and 24.3 million barrels

in product stocks. Since product stocks declined about 12 million barrels in the California district, the increase in the districts east of California amounted to 36 million barrels.

As total imports declined about 1 percent, the increase in new supply in 1951 came from increased production. The production of crude oil set a new record in 1951, averaging 6,149,000 barrels daily, a gain of 742,000 barrels daily or almost 14 percent compared with 1950. Texas supplied 180 million barrels of the total increase of 271 million barrels in crude production.

The production of light oils from natural gas and other sources averaged 564,000 barrels daily in 1951, a gain of 13 percent. About 60 percent of these light oils are included in the output of motor fuel, and most of the remainder are sold as liquefied gases for fuel and chemical uses and are supplemented by the similar products recovered from still gas at refineries.[2]

DEMAND

The domestic demand for all oils[3] in continental United States averaged 7,044,000 barrels daily, or a gain of 8.3 percent compared with 1950. The relative gains of principal products were 9.7 percent for motor fuel, 1.8 percent for residual fuel oil, 13.8 percent for distillate, 4.9 percent for kerosine, and 9.5 percent for all other products. A brief review of the trends in demand for the major oil products follows.

Motor Fuel (Gasoline and Naphtha).—The total demand for motor fuel rose from 1,019 million barrels in 1950 to 1,131 million in 1951, an increase of 112 million barrels or 11 percent. Exports increased from 24.7 million barrels to 40.4 million barrels, a gain of 15.7 million or 63 percent. Domestic demand rose from 994 million barrels to 1,090 million, an increase of 96 million barrels or 10 percent.

The downward trend in exports since 1949, caused by expanding refinery capacity abroad, was reversed in 1951, since a major part of the increasing foreign production was needed to offset the loss in Iran output and was not sufficient to cover the increases in demand. Exports of aviation gasoline, included in the total, rose from 7.1 million barrels in 1950 to 12.2 million in 1951.

The domestic demand for motor fuel continued a steady upward trend with the rapid growth in motor transport and the gain in aviation requirements. The rapid increase in the number of trucks powered by diesel engines, using either diesel oil or liquefied gases, accounted for over 1 percent of the total highway use of fuel in 1951. The domestic demand for aviation gasoline, included in the total, increased from 39.5 million barrels in 1950 to 53.1 million in 1951, the major part of the increase being in deliveries to the Armed Forces. The aviation-gasoline figures do not include jet fuel, a mixture of low-grade gasoline with either light distillate fuel oil or kerosine.

Residual Fuel Oil.—The total demand for residual fuel oil rose from 570 million barrels in 1950 to 593 million in 1951, a 4-percent gain. Exports increased from 16.2 million barrels to 29.1 million, a 79-percent increase. Domestic demand amounted to 554 million barrels in 1950 and 564 million in 1951, a gain of less than 2 percent.

[2] The term "motor fuel" as used in this chapter includes gasoline and naphtha but does not include liquefied gases or distillate fuel oil used subsequently in internal-combustion engines.

[3] For definition, *see* footnote 1 at beginning of this chapter.

TABLE 3.—Demand for all oils [1] in continental United States, 1942–51

[Millions of barrels]

Year	Domestic demand	Exports	Total demand	Year	Domestic demand	Exports	Total demand
1942	1,449.9	116.9	1,566.8	1947	1,989.8	164.5	2,154.3
1943	1,521.4	150.0	1,671.4	1948	2,113.7	134.7	2,248.4
1944	1,671.3	207.6	1,878.9	1949	2,118.2	119.4	2,237.6
1945	1,772.7	183.0	1,955.7	1950	2,375.1	111.3	2,486.4
1946	1,792.8	153.1	1,945.9	1951 [2]	2,571.1	154.4	2,725.5

[1] *See* text footnote 1 at beginning of this chapter.
[2] Preliminary figures.

Exports to Asia and Oceania increased 8.1 million barrels in 1951, to Europe 2.2 million, and to Canada 1.3 million barrels. A major part of the gain in exports was from California and was due to shortages caused by the closing of the refinery in Iran and to a shift in shipments to Japan from our military custody to commercial shipments that are recorded as exports.

The small increase in domestic demand resulted from a combination of diverse factors. The principal gains were about 13 million barrels in residual fuel oil used for bunkering ships engaged in foreign trade, 10 million barrels in deliveries to our Armed Forces, and 9 million barrels in deliveries to mines and industrial plants. The largest declines were 22 million barrels used by manufactured-gas and electric public-utility plants resulting from shifts to coal or natural gas, and 6 million barrels in deliveries to railroads resulting from the further shift to diesel locomotives.

Distillate Fuel Oil.—The total demand for distillate fuel rose from 408 million barrels in 1950 to 472 million in 1951—a gain of 64 million or almost 16 percent. Domestic demand increased 54 million barrels or almost 14 percent, and exports were up 10 million barrels or 79 percent. The principal gains in exports were 3.7 million barrels to other North American countries, 3.0 million to Europe, and 2.3 million to Asia and Oceania. A considerable part of this increase resulted from the shortage outside the United States after closing of the Iran refinery. The largest gains in domestic demand were 28.3 million for heating and 11.3 million for railroad use. The only decline was 3.6 million barrels in deliveries to gas and electric plants.

Kerosine.—The total demand for kerosine rose from 120 million barrels in 1950 to 131 million in 1951—a gain of 11 million or about 9 percent. Domestic demand increased 5.9 million barrels or 5 percent, whereas exports gained 4.7 million or 228 percent. The major increases in exports were to the United Kingdom, Egypt, and India, and resulted from the reduction in normal supply from Iran. Kerosine, as reported by refineries, is a product that meets the specifications for "lamp oil" as to color and flashpoint and goes back to the period when kerosine lamps were in general use. The increased demand has been for such uses as range oil, small space heating, tractor fuel, and one of the constituents of jet fuel. For these purposes it competes with No. 1 distillate.

Other Products.—The total demand for other products includes exports of these products, export of crude oil, and domestic demand for the products, including crude oil used as fuel and losses. The exports of crude oil declined from 34.8 million barrels in 1950 to 28.6

Digitized by Google

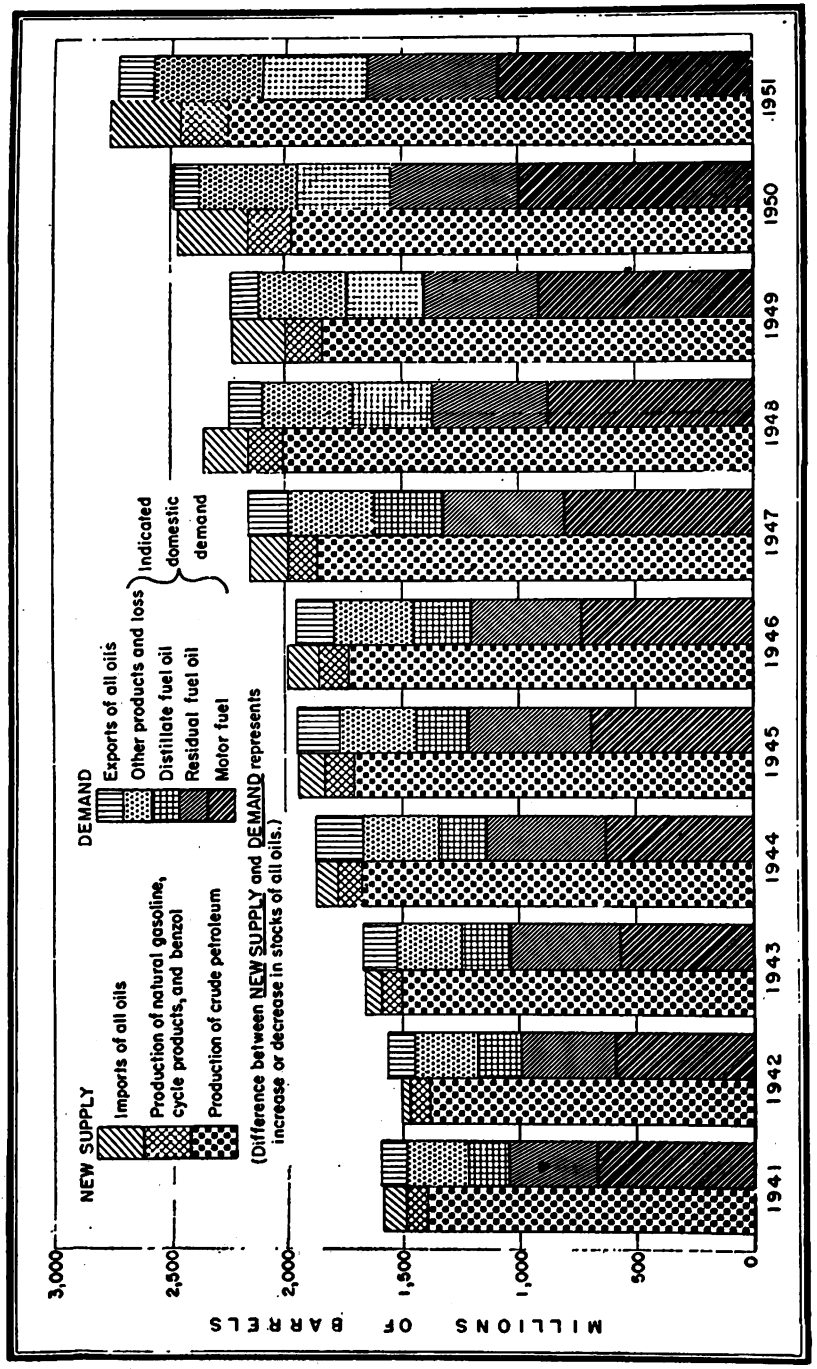

FIGURE 1.—Supply and demand of all oils in the United States, 1941–51.

Digitized by Google

million in 1951. The exports of other refined products rose from 20.8 million in 1950 to 26.9 million in 1951. The domestic demand for other products increased from 314.2 million barrels to 344.2 million in 1951, a gain of 10 percent. The domestic demand for liquefied gases increased almost 21 percent to 103.3 million barrels in 1951; the production of still gas increased 15 percent to 96.3 million barrels; asphalt demand rose to 66.2 million barrels, a gain of 13 percent; and the demand for lubricants and greases amounted to 42.3 million barrels in 1951, an increase of over 9 percent. Total losses, crude oil and refinery shortage, declined from 17.9 million barrels in 1950 to 5.8 million in 1951.

Demand in United States Territories.—In computing domestic demand in continental United States, shipments from the United States to the Territories (and possessions) are included with exports and any imports from foreign countries into the Territories are deleted from total imports. The major part of such shipments from the United States goes to Hawaii, Alaska, and Puerto Rico, whereas Puerto Rico is normally the chief importer of foreign oils.

Table 4, in addition to giving imports and exports of continental United States, shows the receipts of oil products within the Territories and these receipts, less some minor reexports, indicate their total demand. The figures do not include oil moved in the custody of the Armed Forces. Total oil receipts in the Territories rose from 17.1 million barrels in 1950 to the record level of 20.0 million in 1951, a gain of about 24 percent compared with 1946. The indicated demand, after deducting reexports, amounted to about 16.8 million barrels in 1950 and 19.7 million in 1951.

WORLD OIL SUPPLY

World production of crude petroleum increased 12.6 percent, from 3,803 million barrels in 1950 to 4,283 million in 1951. The total increase of 480 million barrels included a gain of 271 million for the United States and an increase of 209 million for the rest of the world. The largest gains in production outside the United States were: Kuwait, 79 million barrels; Saudi Arabia, 78 million; Venezuela, 75 million; Canada, 19 million; U.S.S.R., 19 million; and Iraq, 15 million. The principal decline was 115 million barrels for Iran. The United States produced 51.9 percent of the world total in 1950 and 52.4 percent in 1951.

Total imports of crude oil and products into continental United States exceeded total exports by 199.0 million barrels in 1950 and 153.3 million in 1951. The net import of crude oil rose from 142.9 million barrels in 1950 to 150.5 million in 1951, whereas the net import of oil products declined from 56.1 million barrels in 1950 to 2.8 million in 1951. The increase in exports of refined products from 76.5 million barrels in 1950 to 125.8 million in 1951, due to the refinery shutdown in Iran in the last half of 1951, was the main reason for the decline in net product imports.

The Caribbean countries and Mexico furnished about 86 percent of the total imports into continental United States and the Territories in 1951, including about 77 percent of total crude imports and 98 percent of total product imports.

RESERVES

The Committee on Petroleum Reserves, American Petroleum Institute, estimated proved reserves of crude oil in the United States on December 31, 1951, at 27,468 million barrels, compared with 25,268 million on December 31, 1950. These estimates refer solely to blocked-out reserves, including only oil recoverable under existing economic and operating conditions.

The increase in net crude reserves in 1951 was 2,200 million barrels (8.7 percent). Estimated new reserves added in 1951 were 4,414 million barrels, including an upward revision of 4,025 million, due to extensions of old pools and revisions of previous estimates, and an estimate of 389 million for new reserves discovered in 1951 in new fields and in new pools in old fields. Deduction of an estimated production in 1951 of 2,214 million barrels, exclusive of lease condensate mixed with crude, results in the indicated net gain in total reserves.

[1] From reports of Committee on Petroleum Reserves, American Petroleum Institute, of the amount of crude oil that may be extracted by present methods from fields completely developed or sufficiently explored to permit reasonably accurate calculations. The change in reserves during any year represents total new discoveries, extensions, and revisions, minus production.
[2] Old basis; includes condensate.

The principal changes in net crude-oil reserves in 1951 were gains of 1,733 million barrels for Texas, 132 million for Wyoming, 100 million for Louisiana, 82 million for Illinois, 80 million for Oklahoma, 60 million for Kansas, 27 million for California, and 20 million for New Mexico. The principal declines were 15 million barrels for Michigan, 14 million for Colorado, and 11 million for Pennsylvania.

As of December 31, 1951, Texas had 55.8 percent of the total crude reserves, California 13.7 percent, Louisiana 8.3 percent, Oklahoma 5.4 percent, and Wyoming 3.5 percent.

The total proved reserves of natural-gas liquids, not included in the crude-oil reserves, rose from 4,268 million barrels on December 31, 1950, to 4,725 million at the end of 1951.

CRUDE PETROLEUM

SUPPLY AND DEMAND

The new supply of crude petroleum in the United States averaged 6,640,000 barrels daily in 1951, a gain of 746,000 barrels daily or 12.7 percent compared with 1950. The domestic production of crude oil increased 13.7 percent, whereas crude imports gained only 0.8 percent. The supply of crude oil proved to be more than was required in 1951, as measured by an increase in total crude stocks of 7 million barrels

Digitized by Google

during the year and a gain of 24 million barrels in stocks of refined products.

The total indicated demand for crude oil (new supply plus decreases or minus increases in crude stocks) increased from 2,156 million barrels in 1950 to 2,416 million in 1951, a gain of 260 million or 12 percent. Total crude run to stills at refineries increased from 2,095 million barrels to 2,370 million, a gain of 275 million in 1951 or 13 percent. Crude for all other purposes (export, direct fuel use, and loss) declined 15 million barrels from 61 million to 46 million.

PRODUCTION

GENERAL

The production of crude oil set a new record in 1951 as the result of a gain of 13.7 percent compared with 1950. The increase of 271.0 million barrels in production was distributed very irregularly among the States. The largest gains were 180.3 million barrels for Texas, 26.9 million for California, 23.2 million for Oklahoma, and 22.9 million for Louisiana. There were declines in 8 States, including 3.8 million barrels for Illinois, 1.9 million for Michigan, 1.3 million for Arkansas, and 1.2 million for Mississippi.

Five States produced over 100 million barrels each and accounted for 83.0 percent of the total in 1950 and 84.6 percent in 1951. There has been no change in the order of importance of these States since 1946. Texas, producing 45.0 percent of the national total in 1951, has the widest markets for crude oil and has been most affected by the increasing imports of crude oil.

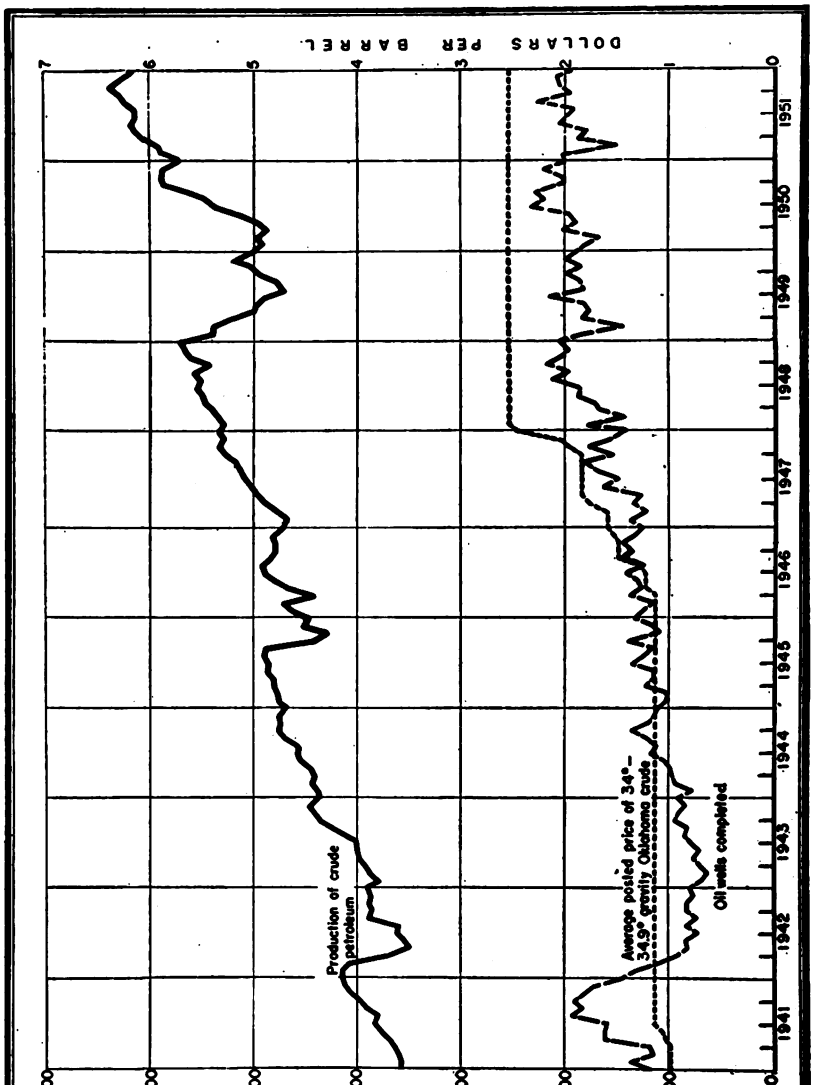

FIGURE 2.—Daily average production of crude petroleum, total number of oil wells completed, and average posted price per barrel of selected grade of Oklahoma crude petroleum in the United States, 1941–51, by months.

Digitized by Google

The next 6 States in importance produced more than 20 million and less than 100 million barrels each. This group produced 13.4 percent of the national total in 1950 and 12.2 percent in 1951. Wyoming replaced Illinois as the sixth State in importance in 1951, and New Mexico, Mississippi, Arkansas, and Colorado followed in order.

The 11 States in the above groups accounted for 96.4 percent of the total production in 1950 and 96.8 percent in 1951. Six of these States—Texas, Louisiana, Oklahoma, Kansas, New Mexico, and Arkansas—issue monthly proration orders under State conservation laws to adjust production to market demand. These States supplied 70.4 percent of national production in 1950 and 72.5 percent in 1951.

CRUDE PRODUCTION BY STATES

Alabama.—Although oil production for the State is relatively unimportant, it has gained substantially—from 462,000 barrels in 1949 to 735,000 in 1950 and to 1,020,000 barrels in 1951. There were 50 wells drilled in 1951, of which 17 were rated as oil producers. This compares with 43 for 1950, when 18 were proved for oil and 1 for gas.

Arkansas.—Crude-oil production of 29,770,000 barrels during 1951 was 1,338,000 barrels or 4.3 percent less than in the previous year, with output declining in almost all fields. Only the Fouke and Wesson fields showed slight increases over 1950. The decline in production in Arkansas, in conjunction with the increase in total United States production, reduced Arkansas' share of the total from 1.6 percent in 1950 to 1.3 percent in 1951—the lowest it has been since 1937.

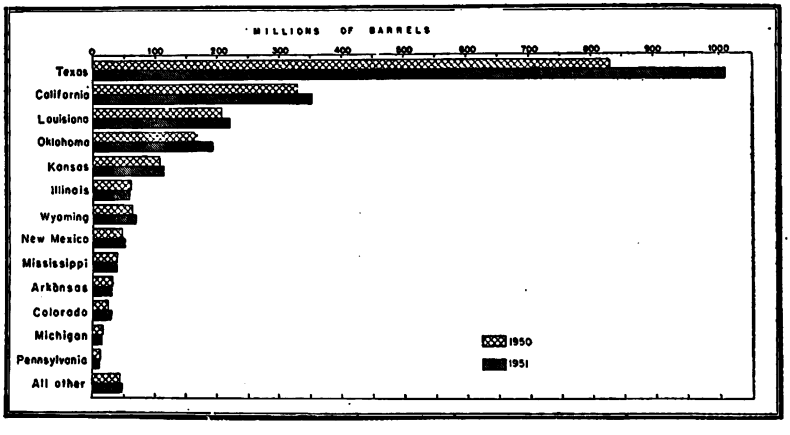

FIGURE 3.—Production of crude petroleum in the United States, 1950–51, by States.

Digitized by Google

Of the 99 wildcat wells drilled during 1951, 13 produced oil, and 1 produced gas, as compared with 10 oil producers out of 100 wildcats in 1950. There was a moderate increase in developmental drilling, with 330 wells completed during 1951 compared with 307 in the preceding year, but the number of successful oil wells fell from 232 to 222 and the percentage of producers from 76 to 67 percent.

Six new pools were discovered in Arkansas during 1951, but none appeared to be especially promising, and only 1 discovery well had an initial production rate over 100 barrels per day. Ten new producing zones in old fields were discovered, and 6 of these had initial production of over 100 barrels per day. The largest producer (320 barrels daily), was in the Travis formation of the old El Dorado field.

California.—Although the 354,467,000 barrels of crude oil produced during 1951 represented an increase of 8 percent over 1950, this rate failed to equal that for the country as a whole, and California's contribution to the total fell from 16.6 to 15.8 percent. This decrease in the share of total production was a continuation of the trend that has been evident since 1948. It is notable that, in spite of the 8-percent increase in California's production, the self-sufficiency of the west coast in the matter of crude oil declined sharply; and receipts from outside sources, both domestic and foreign, rose to 5,246,000 barrels in 1951 compared to 1,448,000 in 1950.

Of the larger fields (those producing over 10,000,000 barrels), all except Buena Vista and Kettleman North Dome increased their output during 1950. Both in quantity (4,726,000 barrels) and percentage (28.6) the Cuyama-Russell Ranch field showed the greatest increase. However, the Wilmington field easily maintained its position as the greatest producing field in the State, increasing its output by 4,572,000 barrels (10 percent) to a total of 50,806,000 barrels. Production in several smaller fields increased substantially, during 1951 with Tejon Ranch, Lompoc, and Zaca Creek more than doubling their 1950 rate and Sansinena almost doubling. Although not generally of large magnitude, there were decreases in production in a great many of the smaller fields.

The need for an effort to provide increased crude-oil productive capacity in California were reflected in the higher rate of drilling activity during 1951. The number of wildcat wells drilled was up 22 percent to a total of 551, and the number of development wells rose 31 percent to 1,810. Somewhat greater success in finding oil was also achieved, with 12 percent of the wildcats resulting in producers during 1951 versus 10 percent in 1950; comparable percentages for developmental wells are 92 and 90.

Colorado.—Production of crude oil during 1951 resumed a relatively sharp rate of increase that was interrupted temporarily in 1950. Total output of 27,225,000 barrels was 17 percent greater than in 1950 and represented a new record for the State. Of the total increase of 3,922,000 barrels, 2,982,000 was concentrated in the Rangely field. The rate of increase over 1950, 17 percent, was greater than that for the entire country. Colorado maintained its position as the eleventh most important producing State and supplied 1.2 percent of total production. Other changes in individual fields were minor and varied, except that the addition of eight new fields of as yet unknown potential resulted in a sharp rise in the "other fields" category.

Wildcat completions during 1951 totaled 143, but only 9 were oil producers and 6 were gas wells. These figures compare with 56 wildcats, 6 producers, and 3 gas wells in 1950. Of development wells, 146 were drilled in 1951 against 43 in the preceding year, and the number of oil producers rose even more sharply—from 16 to 94—and gas wells dropped from 9 to 6.

TABLE 14.—Production of crude petroleum in Colorado, 1947–51, by fields

[Thousands of barrels]

Year	Fort Collins-Wellington	Hiawatha	Iles	Maudlin Gulch	Moffat	Price	Powder Wash	Rangely	Walden	Wilson Creek	Other fields [1]	Total

[1] Includes crude oil consumed on leases and net change in stocks held on leases for entire State.
[2] Preliminary figures.

Florida.—The production of oil, of small volume, increased from 441,000 barrels in 1949 to 487,000 in 1950 and 596,000 barrels in 1951. Drilling fell off sharply from 13 completions (10 of them wildcats), resulting in 1 oil well in 1950 to 2 wildcats in 1951, both of which proved dry.

Illinois.—Crude-oil production continued the decline that began in 1947, and total output of 59,827,000 barrels (Oil and Gas Journal data) during 1951 was 4 percent less than the 1950 total. Although the great majority of the individual fields showed fairly substantial decreases during 1951, there were notable exceptions. Output of the Benton field (2,205,000 barrels) was more than 5 times the 1950 figure, Dale's output about doubled, and New Harmony's production increased almost 50 percent. Albion and Phillipstown fields showed more moderate increases.

Digitized by Google

There was a moderate increase in the number of wildcat wells drilled during 1951 to 873 from 810 in 1950, but the number of oil producers completed fell to 103 from 104. The number of development wells drilled declined sharply from 2,013 in 1950 to 1,551 in 1951, and the number resulting in oil producers showed an even greater relative decrease from 1,176 to 815.

Indiana.—Production of crude oil during 1951 totaled 10,597,000 barrels, only a slight change from the preceding year's total of 10,699,000 barrels. Of some significance is the fact that production accelerated during the latter half of the year. There was also little change in exploratory drilling, with 559 wildcats completed compared with 570 in 1950. Developmental drilling was off sharply; however, the 810 wells completed in 1951 represented a decrease of 154 from 1950, and the 370 oil producers completed showed a decrease of 132.

Kansas.—The 114,094,000 barrels (Oil and Gas Journal data) of crude oil produced during 1951 was an increase of 6.4 percent over 1950 and an alltime record for the State. In spite of this record rate of output, Kansas' share of total United States production fell from 5.5 percent in 1950 to 5.1 percent. Most of the increase in production

Digitized by Google

was achieved in the smaller fields included in the "Other" classification, although the production in the Gorham and Morel fields each increased approximately 1 million barrels.

There was a substantial increase in drilling activity during 1951; 4,501 wells were completed compared to 4,010 in 1950. Wildcat completions rose from 816 to 1,006, and the number of development wells was up from 3,194 to 3,495. However, the degree of success reached in drilling remained unchanged for development wells with about 58 percent of the total number drilled resulting in oil wells in both years, whereas for exploratory wells the proportion of producers fell from 15.7 percent in 1950 to 13.8 percent in 1951.

Kentucky.—During 1951 crude-oil production reached a new record high of 11,622,000 barrels, 1,241,000 barrels or 12 percent greater than in 1950. There was a nominal increase in the number of wells drilled from 1,150 in 1950 to 1,309 in 1951, and the number of successful wells showed an almost parallel increase from 516 to 524.

1950 to 188,756,000 in 1951, whereas, conversely, the quantity produced in Northern Louisiana registered a small decline from 44,210,000 barrels in 1950 to 43,082,000 in 1951.

Gulf Coast fields that reported important percentage gains in crude production in 1951 over 1950 were the Caillou Island, Iowa, Lake Pelto Main Pass, Point-A-La-Hache, Romre Pass, Sunshine, Weeks Island, West Bay, and West Cote Blanche. In addition, various small fields, taken together, accounted for an increased production of 11,650,000 barrels, a gain of 31 percent over the 1950 total for this group. Main Pass, Point-A-La-Hache, and Sunshine, first reported in 1948, developed into fairly important producing fields in 1950 and 1951. Romre Pass, with first production in 1950, had a large increase in 1951.

In the Gulf Coast area, 991 wells were completed in 1951 compared with 1,126 in 1950. The proved oil wells totaled 583 in 1951 and 720 in 1950. The number of wildcat wells drilled in the same area increased from 166—49 of them oil wells—in 1950, to 169—41 oil wells—in 1951. New pools discovered totaled 24 in 1951 and 32 in 1950. Shell 1 Gonsulin, 41–14s–7e, in Iberia Parish was drilled to a record depth of 15,336 feet in 1951 to produce oil in the Miocene formation.

Only 3 of the 11 major fields in Northern Louisiana showed increases in production in 1951 over 1950, and the gains for 2 of these were trivial. Various small fields grouped together were credited with a gain of 21 percent in 1951 over 1950, an increase that counteracted the net decline in the main producing areas.

There were 1,249 wells drilled in Northern Louisiana in 1951 compared with 1,327 in 1950. The number proved for oil also declined from 773 in 1950 to 635 in 1951. Wells drilled in wildcat areas increased from 136 in 1950 to 210 in 1951, and this exploratory drilling resulted in 17 oil wells in both years. New pools discovered in the area declined from 17 in 1950 to 12 in 1951.

Michigan.—The decline in crude-oil production evident since 1948 continued in 1951, when the total (13,923,000 barrels) was 12 percent below the 1950 output of 15,826,000 barrels. All fields in the State reported lower production in 1951 except East Norwich and St. Helen, where gains were only moderate. The 746 wells completed in the State in 1951 were somewhat below the 1950 total of 897. Those proved for oil totaled 223 in 1951, a number well below the 348 reported in 1950. Wildcat wells declined from 338—29 of them oil wells—in 1950 to 332, of which 19 proved to be oil producers in 1951.

[1] Preliminary figures.

Mississippi.—Crude-oil production during 1951—37,039,000 barrels—represented a decrease of 1,197,000 barrels or 3 percent from the preceding year. The first 4 months showed increases, compared with 1950; thereafter each month showed a decrease.

A moderate increase occurred in drilling activity during 1951, with 374 wells drilled compared to 313 wells in 1950. The number of oil wells completed increased from 124 to 137.

[1] Preliminary figures.

Montana.—During 1951 crude-oil production rose somewhat from the low rate of the preceding year, but the total (8,922,000 barrels) was less than in 1948 and 1949. Changes in the rate of well completions were minor, with 262 wells completed in 1951 compared to 270 in 1950.

TABLE 22.—Production of crude petroleum in Montana, 1947–51, by fields, in thousands of barrels

[2] Preliminary figures.

Nebraska.—Although total crude-oil production during 1951 reached a new peak of 2,408,000 barrels—56 percent over 1950—the trend was downward during the year, and for each month after August output was less than in the comparable month of 1950.

Digitized by Google

Drilling activity was up sharply during 1951, with 241 wells completed compared to 171 in 1950. The increased exploratory activity was even more marked, with 134 wildcat wells drilled compared with 82 in 1950.

[1] Preliminary figures.

New Mexico.—Crude-oil production during 1951 rose to a new record of 52,729,000 barrels (Oil and Gas Journal data), about 11 percent above the rate that had prevailed for the preceding 3 years. Almost all the increase is attributable to the "other" fields, that is, fields that are too small to be significant individually but that, in New Mexico, contribute one-third of the total production.

The number of wells completed rose to 773 in 1951 from 607 the preceding year, but this increase is attributable to the large number of gas wells drilled in the Northwest section of the State. The number of oil wells completed actually fell from 396 to 350.

There was great activity in wildcat drilling, expecially in the Southeast part of the State, where the important Permian Basin extends over from Texas. Wildcat wells totaled 105 in 1951, compared with 79 in 1950, and 90 were in the Southeast area, most of them in Eddy and Lea Counties.

New York.—Crude output during 1951 was 4,254,000 barrels, 111,000 barrels greater than in 1950. The increase, although slight, represents the first such change since 1946 and probably reflects the more general application of improved methods of secondary recovery.

Digitized by Google

Drilling activity showed little change during 1951, with 627 wells completed (320 oil wells) compared to 657 (337 oil wells) in 1950.

TABLE 25.—Production of crude petroleum in New York, 1947–51, by months

[1] Preliminary figures.

Ohio.—The downward trend in crude-oil production continued for the third successive year, and 1951 output (3,097,000 barrels) was the lowest since 1946. Drilling activity also decreased, with 971 wells completed in 1951 compared to 1,027 in 1950.

TABLE 26.—Production of crude petroleum in Ohio, 1947–51, by months

[1] Preliminary figures.

Oklahoma.—Crude-oil production during 1951 increased 14 percent over the preceding year to a total of 186,866,000 barrels (Oil and Gas Journal data), the highest since 1937. Of the total increase of 23,023,000 barrels, the smaller fields, reported collectively, contributed 11,704,000 barrels, Sholem-Alechem 2,012,000 barrels, Fox-Graham 2,273,000 barrels, Elk City 2,360,000 barrels, and Velma 5,862,000 barrels.

Although wells completed in Oklahoma increased from 5,459 in 1950 to 5,626 in 1951, those producing oil declined by 6 percent from 3,304 in 1950 to 3,109 in 1951. Wildcat wells declined slightly from 840 in 1950 (163 producing oil) to 830 in 1951, of which 124 were oil wells.

Pennsylvania.—After a slight increase in 1950 over 1949, the downward trend in crude-oil production was again evident in 1951, when the total of 11,150,000 barrels was 6 percent below the 1950 output of 11,859,000 barrels. There were 1,738 wells completed in 1951 compared with 1,581 in 1950. The 1951 developments resulted in 776 oil wells, 239 gas wells, and 70 dry holes.

TABLE 28.—Production of crude petroleum in Pennsylvania, 1947–51, by months

[Thousands of barrels]

Year	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Total
1947	1,110	920	1,017	1,069	1,081	1,057	1,110	1,056	1,072	1,120	994	1,084	12,690

[1] Preliminary figures.

Texas.—The State was credited with nearly half (45 percent) the total crude-oil production in 1951, when the total of 1,010,128,000 barrels was 22 percent over the 1950 output of 829,874,000 barrels. Important increases in crude output were reported for all districts except the Panhandle, where there was a 6-percent decline. The production gain in West Texas in 1951 was outstanding—33 percent—followed by South Texas with a 23-percent increase and the Gulf

Digitized by Google

Coast with an expansion of 20 percent. Central Texas showed an 18-percent gain, and production in both the East and North Texas districts were up by 13 percent.

There was only a nominal gain in the number of wells drilled in Texas in 1951, with a total of 16,615 compared with 16,509 in 1950. All areas except the North Central and the Panhandle showed small gains in wells drilled in 1951 over 1950. Oil-producing wells drilled declined from 10,665 in 1950 to 10,086 in 1951, whereas proved gas wells increased from 647 in 1950 to 726 in 1951. There was a 12-percent gain in dry holes in 1951—5,803 compared with 5,197 in 1950. The average footage for all wells increased from 4,340 to 4,601 feet in 1951.

Gulf Coast.—This district, which accounts for about a fourth of the Texas crude, was credited with a production of 239,104,000 barrels in 1951, or a fifth more than the 1950 total (199,263,000 barrels). Of the numerous fields in the district only nine of them showed losses in 1951 compared with 1950. These declines were all trivial except in the Bay City, down 17 percent, South Liberty, lower by 19 percent, and West Columbia, a drop of 11 percent. Fields, showing largest gains in 1951 over 1950 and which produced relatively important quantities were: Anahuac, 14 percent; Chocolate Bayou, 21 percent; Conroe, 18 percent; Friendswood, 32 percent; Hastings, 25 percent; Old Ocean, 13 percent; Thompson, 26 percent; and West Ranch, 38 percent. Numerous small fields grouped together, which accounted for about 28 percent of the district total in both 1950 and 1951, reported a gain of 21 percent in crude production in 1951 over 1950.

Wells completed in 1951 totaled 2,312 compared with 2,303 in 1950. Completions in 1951 were reported as 1,267 oil wells, 209 gas wells, and 836 dry holes; the 1950 breakdown was 1,390 oil wells, 153 gas wells, and 760 failures. Exploration activities resulted in the discovery of 110 new pools in the Gulf Coast area in 1951 compared with 92 in 1950; and new pays reported totaled 69 in 1951 and 61 in 1950. Records show that 7 wells were drilled below 12,500 feet in 1951 and 6 in 1950.

East Texas.—Fields in the area produced 162,764,000 barrels of crude petroleum in 1951, a gain of 13 percent over the 1950 total of 144,191,000 barrels, comprising about 16 percent of the Texas 1951 production. Three fields in East Texas—Cayuga, Merigale and Rodessa—showed a lower output in 1951 than in 1950, whereas all others reported a gain. More than three-fifths of the crude was credited to East Texas proper, where the gain was about 3 percent in 1951 over 1950. Secondary fields showing important gains in production in 1951 were: Hawkins, 31 percent; Talco, 14 percent; and Van, 32 percent. Various small fields grouped together reported a total of 19,160,000 barrels in 1951, a gain of 68 percent.

The number of wells drilled in East Texas fields increased from 1,152 in 1950 to 1,173 in 1951. Oil wells declined from 801 to 739, and the gas wells dropped from 51 to 30, whereas the dry holes rose from 300 in 1950 to 404 in 1951. Drilling activities resulted in the discovery of 20 new pools and 9 new pay sands in 1951 compared with 13 new pools and 5 pay sands in 1950. Two wells were drilled below 12,500 feet in 1951 and 1 in 1950.

Central Texas.—Only a small proportion—about 1 percent—of the Texas crude production comes from this area; however, the 1951 total

Digitized by Google

of 11,517,000 barrels was 18 percent above the previous year. All fields reported gains, with the Luling field largest—21 percent.

The number of wells drilled in the area dropped slightly from 5,012 in 1950 to 4,990 in 1951. The 1951 explorations resulted in the discovery of 2,424 oil and 50 gas wells. Dry holes totaled 2,516. In 1950, 2,590 oil and 71 gas wells were brought in, and the dry holes numbered 2,351. There were 219 new pools and 19 new pays discovered in 1951, compared with 132 and 14, respectively, in 1950.

North Texas.—Although crude production increased from 79,998,000 barrels in 1950 to 90,208,000 in 1951—a 13-percent gain—the output for the area declined from about 10 percent of the State total in 1950 to less than 9 percent in 1951. Wells completed declined from 2,982—1,637 oil wells, 22 gas wells, and 1,323 dry holes—in 1950 to 2,667—1,378 oil wells, 11 gas wells, and 1,278 dry holes—in 1951. Wildcat drilling, however, increased from 607 wells in 1950 to 862 in 1951. The larger share of the exploratory drilling in 1951 was confined to Archer, Young, Jack, and Cooke Counties, in the order named.

Panhandle.—This was the only producing area to show a decline in 1951, when the output of 31,287,000 barrels was 6 percent below the 1950 total of 33,131,000 barrels.

There was also a decline in drilling activities, as the 727 wells completed were 18 percent below the 889 reported for 1950. A total of 350 wells were proved for oil in 1951, 294 for gas, and 83 were dry. These results compare with 582 oil and 232 gas wells found in 1950 and 75 dry holes. Thirty-six wildcat wells were drilled in 1951, and these proved only 2 oil wells. This record compares with 24 wildcats in 1950, which brought in 1 oil and 2 gas wells.

Five wells were drilled below 10,000 feet in 1950; however, none below this depth were reported during 1951.

South Texas.—Crude-oil production of 94,119,000 barrels in 1951 was about 23 percent over the 1950 output of 76,826,000 barrels, and the quantity in each year represented approximately 9 percent of the State total.

Wells completed in 1951, totaling 2,301, proved 1,253 for oil and 118 for gas; the remaining 930 were dry holes. The comparative totals for 1950 were 2,155 completions, resulting in 1,185 oil and 124 gas wells and 846 dry holes. Three were wells sunk to over 12,500 feet in 1951 compared with 1 in 1950.

Wildcat drilling increased from 628 wells—97 proving oil, 97 gas, and 502 dry holes—in 1950 to 730—101 oil, 40 gas, and 589 dry holes—in 1951. Most of these exploratory activities were centered in Duval, Jim Hogg, Nueces, San Patricio, Starr, and Webb Counties.

West Texas.—About 38 percent of the crude produced in the State came from this area in 1951, and the total (381,129,000 barrels) was a third above the 1950 quantity (286,696,000 barrels). Outstanding gains in production in 1951 were reported for Ector and Scurry Counties. The output credited to Ector County, which makes up part of the Spraberry trend of the Permian Basin, one of the richest known oil deposits in the country, increased by a third from 57,096,000 barrels in 1950 to 75,918,000 in 1951. A similar gain was reported for Scurry County, the center of another important group of fields discovered in recent years, where the output has "skyrocketed" from a minor quantity in 1949 to 36,529,000 barrels in 1950 and to 48,478,000 in 1951. Other counties and districts that showed important gains in

Digitized by Google

crude production in 1951 were Andrews, Crane-Upton, Gaines-Yoakum, Hockley, Pecos, and Winkler.

In this area 5,112 wells were completed in 1951 compared with 4,998 in 1950. Drilling activities proved 4,053 oil and 25 gas wells in 1951, and 1,034 were dry holes. The comparative record in 1950 was 4,117 oil and 16 gas wells and 865 dry holes. Wells classed as wildcats numbered 669 (110 proving oil and 6 gas wells) in 1950 and 844 (189 proving oil and 9 gas wells) in 1951. There were 64 wells drilled below 12,500 feet in 1951 compared with 37 in 1950 and 12 in 1949. One well in Pecos County, a dry hole, was sunk to 15,468 feet in 1951; however, another in Upton County drilled to 13,400 feet struck oil.

Utah.—Crude production of 1,228,000 barrels in 1950 was about double—93 percent—the 1949 total. However this unusual gain was not repeated in 1951, as the output of 1,425,000 barrels was only 16 percent over 1950. There were 39 wells drilled in 1951, resulting in 8 oil wells, 1 gas well, and 30 dry holes. Wildcat drilling (32 wells) proved 3 new pools, 2 oil and 1 gas: 1 for 143 barrels of oil daily in the Basal Green River formation in Duchesne County; a second for 392 barrels of oil daily in the same formation in Uintah County; and a gas well rated at 10,000 M c. f. daily in the Ferron sand of Carbon County.

West Virginia.—A slight decline in crude-oil production was continued for a second year; the 1951 total of 2,743,000 barrels was 2 percent below the 1950 output of 2,808,000 barrels. The 622 wells completed in 1951 (which resulted in 79 oil wells, 419 gas wells, and 124 dry holes) compares with 652 completions in 1950, with 132 oil wells, 384 gas wells, and 136 dry holes. Seventeen wildcats in 1951 brought in 11 gas wells, which compares with 23 gas wells in 1950, the result of 43 exploratory drillings.

Wyoming.—Crude production, which declined 13 percent in 1949, has since turned upward. The 1951 output of 67,932,000 barrels was 10 percent over the 1950 total of 61,631,000 barrels, which in turn was 29 percent above the 1949 quantity. The net gain in production in

1951—6,301,000 barrels over 1950—was due to important increases in the Elk Basin, Sussex-Meadow Creek, Oregon Basin, Byron-Garland, and numerous small fields grouped as 1 unit. Fiddler Creek was the only field to report a large decline in 1951 compared with 1950.

There were 745 wells completed in 1951, which resulted in 442 oil wells, 21 gas wells, and 282 dry holes. This compares with 615 completions in 1950, which brought in 365 oil wells, 18 gas wells, and 232 dry holes. Fourteen new pools were discovered in both 1950 and 1951.

Other States.—In 1951 there was a total production of 77,000 barrels of crude petroleum in other States, including North Dakota, Missouri, Tennessee, and Virginia.

WELLS

The total number of wells drilled in the United States, including oil and gas wells and dry holes, set another new record, rising from 42,030 in 1950 to 43,136 in 1951, a gain of 1,106 compared with a gain of 4,374 wells in 1950. The number of oil wells completed declined from 24,430 in 1950 to 23,453 in 1951, although the number of gas wells and dry holes increased. The program for increased drilling has been stimulated by the recently expanded demand for crude oil and the effort to increase total reserves.

The principal gains in the total number of wells drilled (comparing 1951 with 1950) were 527 in California, 489 in Kansas, 190 in Colorado, 166 in New Mexico, and 161 in Kentucky. The largest declines were 396 in Illinois, 210 in Louisiana, 169 in Indiana, and 137 in Michigan.

The total number of producing oil wells in the United States rose from 465,870 on December 31, 1950, to 474,990 at the end of 1951, and the average production per well increased from 11.8 barrels per day to 13.1.

[3] Alabama, Florida, Missouri, North Dakota, Tennessee, Utah, and Virginia.

CONSUMPTION AND DISTRIBUTION

The indicated total demand [4] for crude oil set a new record in 1951 and amounted to 2,416.3 million barrels—a gain of 12.1 percent compared with 1950. The demand for domestic crude oil increased 12.9 percent to 2,234.1 million barrels and resulted from a production of 2,244.5 million barrels and an increase of 10.4 million barrels in stocks of domestic crude oil. The demand for foreign crude oil increased 3.3 percent to 182.2 million barrels, with imports of 179.1 million barrels and a reduction of 3.1 million barrels in stocks of foreign crude. The demand for foreign crude oil represented 8.2 percent of total crude demand in 1950 and 7.5 percent in 1951.

The total demand for crude oil in 1951 included 2,370.4 million barrels of crude runs to stills at refineries or 98.1 percent of the total. Other demands for crude oil totaled 45.9 million barrels, compared with 61.3 million in 1950. Crude exports declined 6.2 million barrels,

[4] For definition, *see* text footnote 1 at the beginning of this chapter.

Digitized by Google

owing primarily to completion of a new Canadian pipeline to Lake Superior that supplied crude to refineries along the way and began tanker shipments to Ontario in May. Reported transfers of crude for direct use as fuel oil increased from 7.9 million barrels in 1950 to 8.9 million in 1951. Other crude, representing fuel use and losses, decreased from 18.6 million barrels in 1950 to 8.4 million in 1951.

Runs to Stills.—Total crude runs to stills increased from 5,739,000 barrels daily in 1950 to 6,494,000 in 1951, a gain of 13.2 percent. The total increase in runs amounted to 275.5 million barrels, including a gain of 269.8 million in runs of domestic crude and an increase of 5.7 million in runs of foreign crude. Runs of foreign crude increased to 3.6 million barrels in the California district compared with no runs in 1950 and the first trial runs of 1.1 million in 1949. Foreign crude was run for the first time in the Indiana-Illinois district with the beginning of Lake shipments of Canadian crude.

Distribution.—The Bureau of Mines collects data relating to receipts of domestic and foreign crude petroleum at refineries in the United States. These receipts include the crude for total runs to stills at refineries, a small amount of crude used as refinery fuel, and any increase in crude stocks at refineries. Classification of the receipts by States of origin shows the amount received from local production (intrastate), the receipts from other States (interstate), and receipts of imported crude. The classification of receipts by methods of transportation indicates the mode of final delivery—boat, pipeline, or tank cars and trucks. The receipts of domestic crude by boat were, in most instances, originally moved by pipeline from the point of production to the point of shipment by boat.

Receipts of domestic and foreign crude petroleum at refineries amounted to 2,372.0 million barrels in 1951 and—supplemented by a decrease of 1.0 million barrels in crude stocks at refineries—provided for total crude runs of 2,370.4 million barrels and crude used as fuel and losses of 2.6 million barrels. Receipts of foreign crude oil amounted to 179.1 million barrels (7.6 percent of the total), interstate receipts of domestic crude were 901.7 million barrels (38.0 percent of the total), and intrastate receipts of 1,291.2 million barrels represented 54.4 percent of the total.

Of the total refinery receipts of crude petroleum in 1951, 74.1 percent was delivered by pipeline, 24.5 percent by boat, and 1.4 by tank cars and trucks.

Deliveries to refineries by boat totaled 581.5 million barrels in 1951. The delivery of foreign crude oil totaled 178.7 million barrels, including 171.9 million to the East Coast, 3.1 million to the Gulf Coast, 3.6 million to the California district, and 0.1 million to Michigan refineries. The interstate movement of domestic crude oil by boat amounted to 256.9 million barrels, including 191.5 million shipped from the Gulf Coast to the East Coast district, 52.8 million of exchanges by boat between the Texas Gulf and Louisiana Gulf districts, 12.0 million barrels representing river shipments to Kentucky refineries, and 0.6 million barrels to Illinois, Minnesota, and Wisconsin

refineries. Intrastate deliveries by boat amounted to 145.9 million barrels, including 57.3 million barrels in California, 42.0 million in the Louisiana Gulf district, 37.6 million in Texas, and 9.0 million in Kentucky.

Grand total	1,855.6	2,046.6	1,945.5	2,100.4	2,372.0

[1] Preliminary figures.

Demand by States of Origin.—The demand for domestic crude oil increased 254 million barrels in 1951 to a total of 2,234 million. It exceeded 50 million barrels in 8 States. The total demand in these States for crude oil amounted to 2,070 million barrels, or 92.6 percent of the national total in 1951, compared with 91.6 percent in 1950.

Texas, the leading State in supplying the market demand for crude oil, contributed 41.6 percent of the total in 1950 and 45.1 percent in 1951. The demand for Texas crude oil increased about 184 million barrels in 1951, a gain of over 22 percent. Receipts of Texas crude oil at refineries rose from 812.5 million barrels in 1950 to 997.6 million in 1951, an increase of 185.1 million. The principal changes in receipts compared with 1950, were increases of 100.7 million in intrastate receipts at Texas refineries, a gain of 40.6 million in receipts of Texas crude oil at refineries in the Indiana-Illinois district, and an increase of 34.5 million barrels to East Coast refineries due partly to the small gain in receipts of foreign crude.

California ranked second in the demand for domestic crude oil and supplied 16.9 percent of the total in 1950, compared with 15.9 percent in 1951. Demand for California crude increased 21.8 million barrels in 1951, a gain of 6.5 percent, whereas intrastate receipts by refiners in California and Washington increased 23.8 million barrels. Receipts of foreign crude at California refineries amounted to 3.6 million barrels compared with no imports in 1950.

Louisiana ranked third in importance, supplying 10.6 percent of the total demand for domestic crude in 1950 and 10.3 percent in 1951. The demand for Louisiana crude increased 21.7 million barrels in 1951 or 10.3 percent. Total receipts of Louisiana crude at refineries amounted to 229.5 million barrels in 1951, an increase of 26.9 million, including increases of 8.9 million at Louisiana refineries, 11.7 million at refineries in the Indiana-Illinois district, and 10.1 million at Texas refineries; receipts of Louisiana crude in the East Coast district declined 3.3 million.

Oklahoma was fourth in importance, furnishing 8.3 percent of the total demand for domestic crude in 1950 and 8.4 percent in 1951. The demand for Oklahoma crude oil increased 22.6 million barrels or 13.7 percent in 1951. Total receipts of Oklahoma crude at refineries increased 17.8 million barrels in 1951, including gains of 4.5 million at Oklahoma refineries, 6.0 million at refineries in the Indiana-Illinois district, and 4.1 million at refineries in the Appalachian district.

Kansas, fifth in rank, supplied 5.4 percent of the total demand for domestic crude in 1950 and 5.1 percent in 1951. The demand for Kansas crude oil increased 8.7 million barrels or 8.2 percent in 1951. Total receipts of Kansas crude oil at refineries were 112.2 million barrels in 1951, including 60.6 million at Kansas refineries and 51.6 million at refineries in other States. Intrastate receipts increased 1.3 million barrels. Receipts of Kansas crude in the Indiana-Illinois district rose from 35.4 to 37.8 million barrels and those at Oklahoma refineries rose from 10.4 to 11.9 million barrels in 1951.

Wyoming, the sixth State, outranked Illinois in 1951; it supplied 3.2 percent of the demand for domestic crude in 1950 and 2.9 percent in 1951. The demand for Wyoming crude amounted to 65.5 million barrels in 1951, an increase of 1.9 million or a gain of 3 percent. Receipts of Wyoming crude at refineries totaled 65.4 million barrels in 1951, a gain of 4.1 million barrels. Intrastate receipts totaled 27.9 million barrels, an increase of 2.5 million. Receipts of Wyoming

[1] Negative figure represents average. [2] Represents a total movement of crude oil to refineries within the State (intrastate) and in other States (interstate). [3] Pipeline.

Digitized by Google

crude at refineries in other Mountain States were 17.9 million barrels, a gain of 2.4 million. Receipts in the Indiana-Illinois district and the Oklahoma-Kansas district were 18.8 million barrels, a decline of 0.4 million compared with 1950.

Illinois dropped to seventh place in supplying the demand for domestic crude oil, dropping from 3.3 percent of the total in 1950 to 2.5 percent in 1951. The demand for Illinois crude oil declined 13.6 percent from 64.8 million barrels in 1950 to 56.0 million in 1951 as the result of a downward trend in production. The primary markets for Illinois crude oil are in the Indiana-Illinois and Appalachian refinery districts.

New Mexico, ranking eighth, supplied 2.4 percent of the total demand for domestic crude oil in both 1950 and 1951. The demand for New Mexico crude amounted to 52.6 million barrels in 1951, a gain of 4.1 million or 8.5 percent. Receipts of New Mexico crude at refineries in 1951 totaled 50.6 million barrels, an increase of 1.9 million. Intrastate receipts amounted to 4.5 million barrels; receipts in Texas were 27.9 million, in the Indiana-Illinois district 15.5 million, in the East Coast 2.1 million, and in Oklahoma 0.6 million. The principal increase was 1.9 million barrels in the Indiana-Illinois district.

STOCKS

Stocks of all oils rose from 582.7 million barrels on the first of the year to 615.1 million at the end of the year, an increase of 32.4 million barrels during 1951, including gains of 7.3 million for crude oil, 0.8 million for natural-gas liquids, and 24.3 million barrels for refined stocks.

The principal changes in domestic crude-oil stocks, by origin, in 1951 were gains of 3.6 million barrels for Texas, 2.5 million for Wyoming, 2.1 million for Illinois, and 0.7 million each for Oklahoma, Louisiana, and Mississippi. The chief decline was 1.6 million barrels for California.

The increase in refined stocks indicated that crude production and refinery runs were substantially in excess of demand. The increase of 24.3 million barrels in refined stocks included a gain of 36.3 million barrels in districts east of California and a decline of 12.0 million barrels in the California district.

TABLE 41.—Stocks of crude petroleum, natural-gas liquids, and refined products in continental United States at end of year, 1947–51

PRICES AND VALUE

The average value of crude petroleum at the well, as reported in the annual survey of the Bureau of Mines, rose from $2.51 per barrel in 1950 to $2.53 in 1951. The total value of crude petroleum at the well amounted to $4,963 million in 1950 and increased to $5,682 million in 1951, as a result of the increase of 2 cents per barrel and the gain of 13.7 percent in the volume of production.

The average value of crude oil at the well varies with the quality of the oil and the distance from market. The highest value crudes, owing to their high content of lubricants, originate in the Appalachian district. The value of crude from the Illinois basin is well above the average because of quality and nearness to refinery and product markets. The value of crude in Oklahoma and Kansas is slightly above the average, the good quality being somewhat offset by distance from markets. The value of Texas crude is a little above the average and is affected by the relative changes in the volume of production in the wide range of values owing to quality and location.

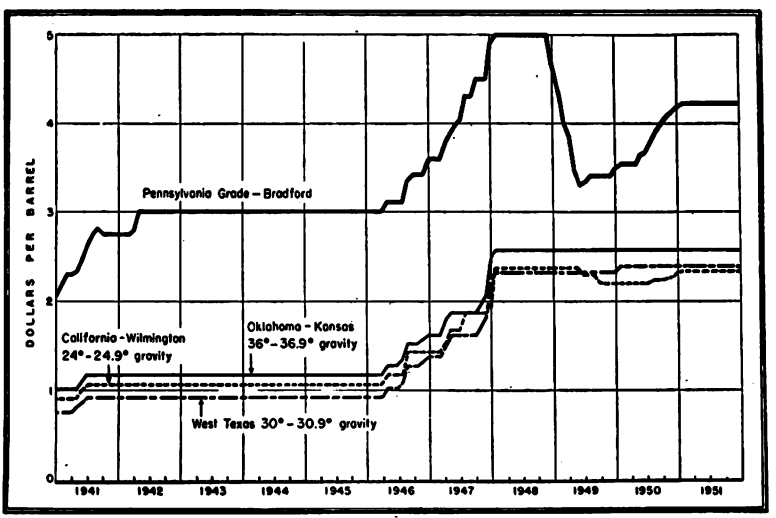

FIGURE 5.—Posted prices of selected grades of crude petroleum in the United States, 1941–51, by months.

The principal 1951 changes in value at the well by States include a sharp rise of 45 cents per barrel for New York, and similar increases for Pennsylvania and West Virginia; a gain of 9 cents per barrel for California, reflecting a relative scarcity of crude oil in relation to increased military demands and product exports; and declines of 7 cents per barrel in Mississippi and 5 cents in Montana. Changes for other States were relatively small and reflect local conditions or a shift in the volume of production between high and low value crudes.

There were no changes in the posted prices shown for representative types of crude in 1951. Only in the case of Pennsylvania Grade crudes and California crudes, which trended upward in 1950, would these figures indicate any increase in average prices in 1951.

REFINED PRODUCTS

GENERAL REVIEW

The total demand for all oils [5] averaged 7,467,000 barrels daily in 1951, a gain of 655,000 barrels daily or 9.6 percent. This increase in total demand included an abnormal increase in the exports of refined products, due to a shortage in the supply outside the United States after the closing of the Abadan refinery in Iran and a substantial gain in domestic demand in continental United States that included a material increase in the delivery of products to our Armed Forces for use at home and abroad. The increase of 13 percent in crude input at refineries, compared with 1950, was relatively higher than the gain in total demand because of the increase of 24.3 million barrels in refined stocks in 1951, compared with a decline in such stocks in 1950 of 16.0 million barrels.

The new supply of refined products comprises the volume of refinery output from crude oil, production of light products from natural gas, and imports of refined products. Crude runs to stills increased from 2,094.9 million barrels in 1950 to 2,370.4 million in 1951, a gain of 275.5 million barrels or over 13 percent. The production of light oils recovered from natural gas plus a small amount of motor benzol from coke ovens rose from 182.1 million

[5] For definition, *see* text footnote 1 at the beginning of this chapter.

Digitized by Google

barrels in 1950 to 205.7 million in 1951, a gain of 23.6 million barrels or 13 percent. Imports of refined products declined from 132.5 million barrels in 1950 to 128.6 million in 1951, a drop of 3.9 million barrels or 3 percent.

The marketed production of the light oils, other than crude, amounted to 204.9 million barrels in 1951, after the increase of 0.8 million barrels in stocks is deducted. Of this total, 129.0 million barrels was blended with gasoline, either at refineries, or outside points, or exported as such. The remaining 75.8 million barrels was mainly sold as liquefied gases for fuel and chemical use (72.4 million) or represented a small amount (3.4 million) of distillate and kerosine produced.

Total output	1,922,938	2,107,278	2,124,567	2,029,678	2,189,506	2,469,654

[1] Includes California data on a new basis to compare with subsequent years.
[2] Preliminary figures.
[3] Conversion factors: 280 pounds of wax to the barrel; 5.0 barrels of coke to the short ton; 5.5 barrels of asphalt to the short ton; 3,600 cubic feet of still gas to the barrel.
[4] Negative quantity; represents net excess of unfinished oils rerun over unfinished oil produced.
[5] Includes losses or gains (parentheses) in volume during processing.

Imports of refined petroleum products in 1951 totaled 128.6 million barrels, including 118.7 million barrels of residual fuel, 1.9 million of distillate fuel, 0.4 million of motor fuel, 2.4 million of asphalt, and 5.2 million of unfinished oils for further refining. The only products to show an increase over 1950 were motor fuel and asphalt. Product imports exceeded refined exports by 56 million barrels in 1950 and by only 3 million in 1951.

[1] Preliminary figures.
[2] Figure on new basis due to transfers in California of stock formerly reported as distillate and residual fuel oils to "Other unfinished oils" and exclusion of the following quantities from distributors' stocks: Kerosine, 115; distillate fuel oil, 1,469; residual fuel oil, 529. Figures for 1948 on the old basis and comparable with preceding years are as follows: Kerosine, 24,056; distillate fuel oil, 76,001; residual fuel oil, 76,970; other unfinished oils, 46,362.
[3] Figure on new basis due to additional terminal storage reported on the East Coast; figure on the old basis, 75,207.
[4] Beginning January 1949 for California, crude petroleum intended for charging cracking units excluded from transfers and considered as run to stills. Figure for 1948 on new basis and comparable with subsequent years, 6,699. Consequent adjustments were made in production.
[5] Beginning with January 1948, exports of grease were transferred from "Miscellaneous" to "Lubricants."
[6] Figure on new basis that excludes distributors' stocks in California and is comparable with subsequent years. Figures for 1947 on the old basis and comparable with preceding years are as follows: Lubricants, 8,624; asphalt 4,021; miscellaneous, 584.
[7] Negative quantity; represents net excess of unfinished oils produced over unfinished oils rerun.
[8] Products from natural gasoline plants added to unfinished oil stocks.
[9] Figures in parentheses represent overage.

Exports of refined products rose from 76.5 million barrels in 1950 to 125.8 million in 1951, a gain of 64 percent. Of the total increase in exports in 1951 of 49.3 million barrels, motor fuel gained 15.6 million, residual 12.8 million, distillate 10.0 million, kerosene 4.7 million, and other products 6.1 million. The largest gains in exports were to Western Europe, southern and eastern Asia, and Oceania—areas formerly receiving products from Iran.

The domestic demand in continental United States rose from 2,375 million barrels in 1950 to 2,571 million in 1951, a gain of 8.3 percent. Increases by products were 9.7 percent for motor fuel, 1.8 percent for residual fuel, 13.7 percent for distillate fuel, 5.0 percent for kerosine, and 9.5 percent for other products. All of these products are discussed separately in subsequent sections of this report.

Stocks of refined products increased from 326.9 million barrels to 351.1 million in 1951, a gain of 24.2 million, including a decline of 12.0 million in the California district and a gain of 36.3 million in all other districts.

[1] Yields computed on the new basis for California to compare with subsequent years.
[2] Preliminary figures.
[3] Not separated after 1946.
[4] Less than 0.1 percent.
[5] Negative percentage; represents excess rerun over produced.
[6] Added to finished gasoline production in computing yields after 1946.
[7] Added to crude in computing yields after 1946.

The change in stocks, by principal products, were gains of 8.0 million barrels for finished and unfinished gasoline, 8.8 million for distillate fuel oil, 5.2 million for kerosine, 1.2 million for residual fuel oil, and 1.0 million for other products. In the California district there were declines in all groups, including 1.1 million for finished and unfinished gasoline, 4.0 million for distillate, 3.6 million for residual, 0.2 million for kerosine, and 3.0 million for other products.

[1] Conversion factors: 280 pounds of wax to the barrel; 5.0 barrels of coke to the short ton; 5.5 barrels of asphalt to the short ton; 3,600 cubic feet of still gas to the barrel.
[2] Negative quantity; represents net excess of unfinished oils rerun over unfinished oils produced.
[3] Figures in parentheses represent overage.
[4] Preliminary figures.

The prices of certain representative products in specified markets have been shown in the Minerals Yearbook over a series of years as a general indication of price trends.

The average value of Regular Grade gasoline at Oklahoma refineries rose from 10.32 cents per gallon in 1950 to 10.56 cents in 1951. The average tank-wagon price of kerosine at Chicago rose from 15.36 cents per gallon in 1950 to 15.80 cents in 1951. The average price of a selected bright stock at Oklahoma refineries rose from 21.21 cents per gallon in 1950 to 29.25 cents in 1951. The average price of Bunker "C" oil at New York rose from $2.09 per barrel in 1950 to $2.32 in 1951. The price of No. 2 distillate-heating oil at New York rose from 8.35 cents per gallon in 1950 to 9.15 in 1951.

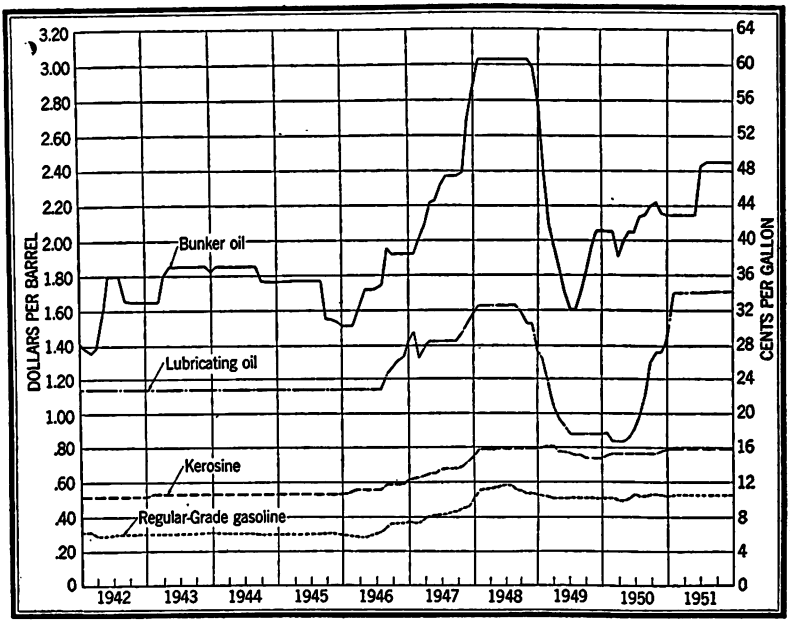

FIGURE 7.—Prices of Bunker "C" oil at New York Harbor, bright stock at Oklahoma refineries, tank-wagon prices of kerosine at Chicago, and Regular Grade gasoline at refineries in Oklahoma, 1942–51, by months.

REFINERY CAPACITY

The total reported crude capacity of refineries in the United States increased from 6,964,000 barrels daily on January 1, 1951, to 7,333,000 barrels daily on January 1, 1952—a gain of 369,000 barrels daily or 5.3 percent. The principal increases in capacity in 1951, by refinery districts, were gains of 131,000 barrels daily in the Texas Gulf, 83,000 in the Indiana-Illinois district, 71,000 in the East Coast, 43,000 in the Oklahoma-Kansas district, and 39,000 in the Texas Inland district.

Digitized by Google

The total capacity under construction was 283,000 barrels daily, including 84,000 in the Indiana-Illinois district, 59,000 in the Oklahoma-Kansas district, and 46,000 in the California district.

In the 3 years from January 1, 1949, to January 1, 1952, total crude-oil capacity at refineries increased 894,000 barrels or almost 14 percent. The largest gains during this period were 251,000 barrels daily in the Indiana-Illinois district, 196,000 barrels in the Texas Gulf, 163,000 barrels in the East Coast, 119,000 barrels in the Oklahoma-Kansas district, and 56,000 in the California district.

TABLE 53.—Petroleum-refinery capacity in the United States, January 1, 1947–52

Year	Number of refineries				Capacity (barrels per day)			
	Operating	Shut down	Total	Building	Operating	Shut down	Total	Building
1947	361	38	399	.....	5,336,399	233,083	5,569,482	162,200
1948	352	38	390	2	5,825,566	208,686	6,034,252	367,250
1949	336	39	375	3	6,230,505	208,490	6,438,995	341,500
1950	320	47	367	2	6,222,998	473,302	6,696,300	145,600
1951	325	32	357	1	6,701,815	261,829	6,963,644	160,100
1952	327	23	350	.....	7,161,366	171,519	7,332,885	282,680

AVIATION GASOLINE

The total demand for aviation grades of gasoline rose from 46.6 millions barrels in 1950 to 65.2 million in 1951, an increase of 18.6 million barrels or 40 percent. This increase was due almost entirely to a gain in exports and to a large increase in military requirements. Exports amounted to 7.1 million barrels in 1950 and 12.2 million in 1951. Exports in the last half of 1951 almost doubled compared with the first half. Domestic demand in the continental United States increased from 39.5 million barrels in 1950 to 53.0 million in 1951, a gain of 13.5 million. This domestic demand included reported deliveries to the Armed Forces that rose from 19.9 million barrels to 33.2 million.

The total demand for aviation grades of 100-octane and above rose from 37.6 million barrels in 1950 to 55.1 million in 1951, whereas the demand for lower grades and components rose only from 9.0 million to 10.1 million.

All aviation-gasoline figures are included in the total figures for motor fuel and gasoline in this chapter. It should be noted that the term "transfers out" represents rejected material returned for use as automotive gasoline; this item is subtracted from the gross production of aviation gasoline to determine the net production of marketable grades.

The data for aviation gasoline do not represent the total fuel used for aviation purposes. The use of jet fuels, blended from low-grade gasoline and either kerosine or distillate fuel, is expanding rapidly. A considerable number of small planes may use automotive types of gasoline.

MOTOR FUEL (GASOLINE AND NAPHTHA)

The total demand for motor fuel set another new record of 1,131 million barrels in 1951, a gain of about 112 million barrels or 11 percent compared with 1950. Total exports increased 15.6 million barrels or 63 percent, including an increase of 5.1 million barrels in aviation grades. The gain in total exports was due, primarily, to the shortage abroad after the shutdown of the oil industry in Iran. Domestic demand in continental United States rose from 994 million barrels in 1950 to 1,090 million in 1951, a gain of 96 million or almost 10 percent, and included an increase of 14 million barrels in the domestic demand for aviation grades.

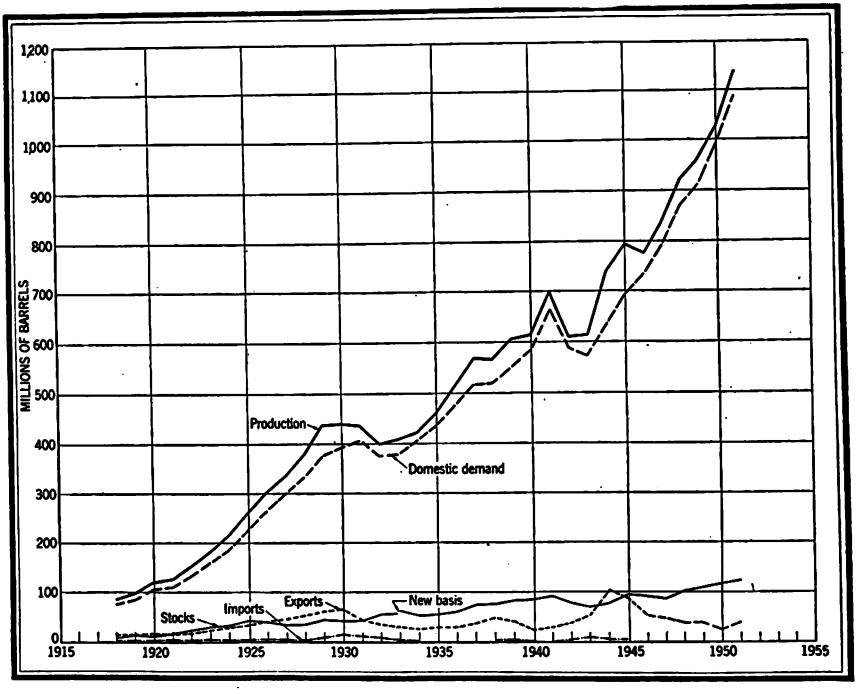

FIGURE 8.—Production, domestic demand, exports, imports, and stocks of motor fuel in the United States, 1918–51.

Production.—The total production of motor fuel rose from 1,024.5 million barrels in 1950 to 1,139.5 million in 1951. Production in 1951 included an output of 1,009.6 million barrels of gasoline and naphtha from crude oil and a net production of natural-gas liquids from natural gasoline and allied plants and motor benzol from coke ovens amounting to 129.9 million barrels. This latter figure was obtained by subtracting from the total output of such oils of 205.7 million barrels the production of 75.8 million barrels used for products other than motor fuel—liquefied petroleum gases and some kerosine and distillate fuel classed as transfers of cycle products. Including imports of motor fuel of 0.4 million in addition to the net production of 1,139.5 million barrels, the total new supply was 1,139.9 million. Deducting the increase in combined stocks of finished gasoline and natural-gas liquids of 9.2

[1] Preliminary figures.

[2] Based on crude runs to stills adjusted for net change in stocks of unfinished oils.

Digitized by Google

million barrels results in the total demand for motor fuel of 1,130.7 million barrels in 1951.

Yields.—The average refinery yields of gasoline and naphtha from crude oil declined from 43.0 percent in 1950 to 42.4 percent in 1951. This decline in yield was related to the gain in distillate fuel yields from 19.0 percent to 20.0 percent, inasmuch as the gain in crude runs of 13 percent was higher than that in total gasoline demand and lower that that in distillate fuel total demand. Even with the reduced yield for gasoline, there was a substantial gain in the stocks of finished gasoline in 1951.

Exports.—Exports of motor fuel from continental United States, including shipments to the Territories and possessions, rose sharply from 24.7 million barrels in 1950 to 40.4 million in 1951, a gain of 63 percent. Exports in the first half of the year amounted to 14.2 million barrels and were 26.2 million in the last half, as the result of the shutdown in the Iran refinery. Exports of motor fuel to the Territories increased from 5.9 million barrels in 1950 to 6.9 million in 1951. Exports of aviation gasoline rose from 7.1 million barrels in 1950 to 12.2 million in 1951.

Total motor-fuel exports to foreign countries increased from 18.8 million barrels in 1950 to 33.5 million in 1951, an increase of 14.7 million barrels.

Domestic Demand.—The domestic demand for motor fuel set another new record and increased from 994 million barrels in 1950 to 1,090 million in 1951, a gain of 96 million or almost 10 percent. Domestic demand averaged 2,987,000 barrels daily in 1951, compared with 2,724,000 barrels daily in 1950.

The annual survey of the Bureau of Public Roads includes an analysis of civilian motor-fuel consumption based on tax returns from the States. The total shown in this survey is considerably smaller than the domestic demand shown by the Bureau of Mines. The difference represents the exclusion from the survey of deliveries to the Armed Forces of most of the naphtha used for industrial purposes and of some losses in production and transportation before the point of tax incidence. On the other hand, the survey includes, in addition to gasoline, an increasing amount of diesel fuels used by trucks.

In 1950 the total motor fuel consumed shown by the Bureau of Public Roads amounted to 959.0 million barrels, including 848.9 million for highway use, 99.4 million for reported nonhighway use, and 10.7 million barrels allowed for losses. The total and the highway use included 12.2 million barrels of special fuels other than gasoline, primarily diesel oil and liquefied gases. In 1951 total usage was 1,022.6 million barrels, including 907.8 million for highway use, 103.4 million for nonhighway uses, and 11.4 million barrels allowed for losses. Special fuels, other than gasoline, amounted to 16.3 million barrels with only 3 States not reporting, compared with 4 States in 1950. Total highway use showed a gain of 9.9 percent in 1950 and an increase of 6.9 percent in 1951.

Production and Consumption by States.—Table 59, showing production and consumption of gasoline by States, is designed to indicate roughly the areas of surplus production and deficit supply. The refinery-production figures are compiled from reports to the Bureau of Mines and do not include the natural gasoline used outside refineries. The consumption figures are compiled by the American Petroleum Institute from State tax reports. These figures are closer

Digitized by Google

to the domestic-demand figures of the Bureau of Mines than those of the Bureau of Public Roads, as they include deliveries to the Armed Forces for use in continental United States, although they do exclude shipments to our Armed Forces abroad.

In 1951 refinery production amounted to 1,109 million barrels and domestic consumption to 1,045 million, an excess production of 64 million barrels. The production figure includes a large part of the motor fuel for export as well as part of the increase in stocks during the year.

Comparison of production and consumption in 1951, by broad districts, indicates the major distribution between surplus and deficit areas. The Gulf Coast States (including Texas, Louisiana, Mississippi, and Alabama) reported a refinery production of 405 million barrels compared with a consumption of 125 million—a surplus of 280 million. The known movements out of this district included shipments to the Atlantic States of 180 million barrels by boat and 16 million by pipeline; shipments north and west to other States include 28 million barrels by pipeline and 3 million by river barges. This district also supplied a considerable part of the exports.

The Atlantic Coast States produced 158 million barrels of motor fuel in 1951 and consumed 332 million—a deficit of 174 million barrels. Receipts from the Gulf Coast district of 180 million barrels by boat and 16 million by pipeline more than supplied this deficit and provided for a pipeline movement of about 2 million barrels west through Pennsylvania and some exports and military deliveries.

The Pacific Coast States (California, Oregon, Washington, Nevada, and Arizona) produced 151 million barrels of motor fuel and consumed 144 million. The surplus of 7 million barrels, which was supplemented by 1 million taken from stocks, was available for export and small shipments to other States.

The Mountain States (Montana, Idaho, Wyoming, Colorado, Utah, and New Mexico) produced 40 million barrels of motor fuel in 1951 and consumed 37 million barrels, leaving a surplus of 3 million barrels, which was the balance of receipts from and shipments to the Pacific Coast district and States to the east.

The remaining Central States produced 354 million barrels in 1951 and consumed 408 million barrels, indicating a deficit of 54 million. Most of this deficit was supplied from the Gulf States, but some shipments were received from the Atlantic Coast and Mountain States.

Although by no means complete, the review of data in this table gives a fair idea of the general distribution and consumption of motor fuel.

Methods of Distribution.—The expansion of product pipelines has resulted from the effort to secure a cheaper long-distance movement to inland markets in the upper Middle West and the inland areas of the Atlantic Coast States. The steady increase in the demand for motor fuel and the rapid gain in the consumption of distillate fuel oil for domestic heating have increased the volume of such movements.

In 1951 deliveries by the product lines totaled 454 million barrels—61 million more than in 1950. Deliveries of motor fuel amounted to 344 million barrels, a gain of 37 million compared with 1950, and represented 75.7 percent of total deliveries, compared with 77.9 percent in 1950. Deliveries of distillate fuel were 88 million barrels in 1951, a gain of 22 million, and increased from 16.9 percent of the total in 1950 to 19.4 percent in 1951. Deliveries of kerosine were 22 million barrels in 1951, an increase of 2 million, and represented 5.2 percent of total deliveries in 1950 and 4.9 percent in 1951. All three of these products can be shipped through the same line without much loss from intermingling at the point of contact.

Tanker movements of motor fuel from the gulf to the East Coast district increased from 167 million barrels in 1950 to 180 million in 1951. There were no shipments of motor fuel from California to the East Coast district in 1951, compared with 6 million barrels in 1950.

Stocks.—Stocks of finished gasoline, as reported, include stocks held at refineries, bulk terminals, and by pipelines but not stocks in secondary distribution tanks, consumers' hands, or military custody. Stocks of finished gasoline increased 8.4 million barrels in 1951—from 108.7 million barrels on the first of the year to 117.1 million on December 31.

Stocks may be expressed in terms of days' supply by dividing the stocks at the end of a month by the daily average total demand for the succeeding month. On this basis, stocks of finished gasoline represented 40.6 days' supply in December 1951 compared with 40.9 days' supply in December 1950.

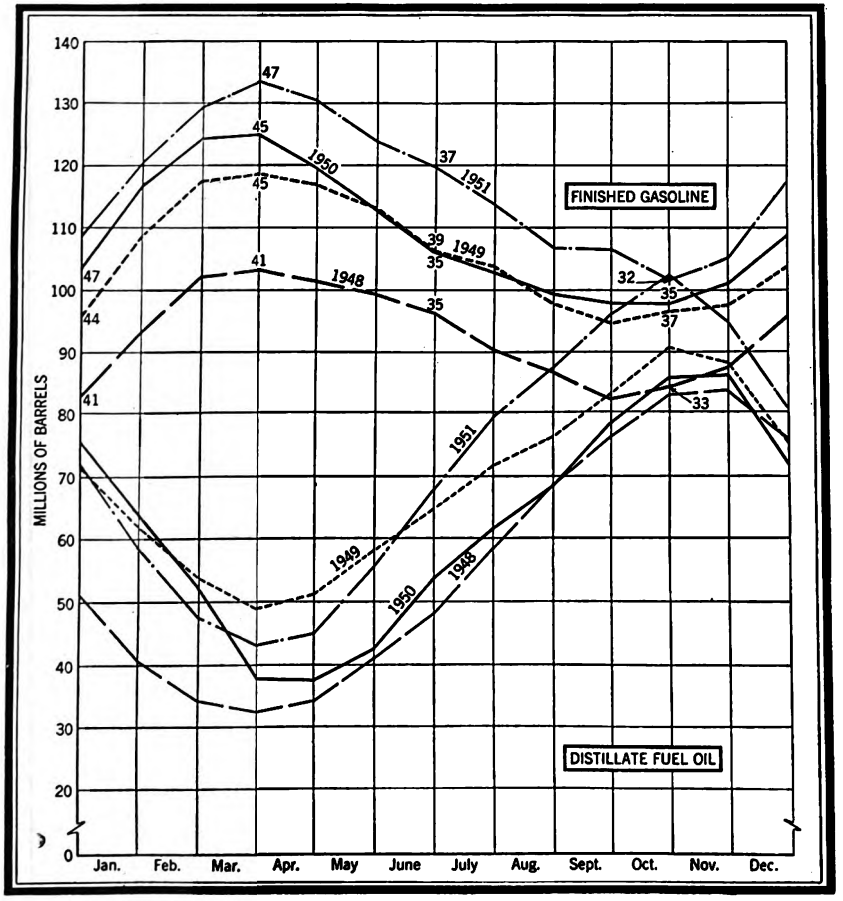

FIGURE 9.—Stocks of finished gasoline in the United States, 1948–51, by months, with figures representing days' supply at certain periods, and stocks of distillate fuel oil, 1948–51, by months.

[2] Preliminary figures.

Prices.—The average dealers' net price for Regular Grade Gasoline (exclusive of taxes) in 50 representative cities in the United States provides an index of gasoline prices at the wholesale level. This average price, according to the American Petroleum Institute, rose from 15.10 cents per gallon in 1950 to 15.33 cents in 1951. Also reported by the American Petroleum Institute, the average service-station price, including all State, local, and Federal taxes, rose from 26.76 cents per gallon in 1950 to 27.15 cents in 1951. The average State tax rose from 5.09 cents per gallon to 5.16 cents, the average local tax (municipal and county) of 0.09 cent remained the same, and the average Federal tax increased from 1.5 cents per gallon in 1950 to 1.59 cents in 1951, owing to the increase in the rate effective November 1, 1951, from 1.5 cents to 2.0 cents per gallon.

OTHER REFINED PRODUCTS

KEROSINE

With the 1951 production of kerosine 15 percent above the 1950 total, the supply was not only sufficient to meet an increased domestic demand (5 percent over 1950) and greatly expanded exports, but there was also a surplus to add to storage. These conditions were a change from those prevailing in 1950, as the production in that year, although well above the 1949 level, had to be augmented by small quantities derived from stocks and imports to satisfy domestic and export requirements.

The greater output of kerosine in 1951 was due almost entirely to a large increase (13 percent) in runs at refineries, as the gain in percentage yield was only trivial.

All areas showed a gain in kerosine production in 1951 over 1950, except the Oklahoma-Kansas and California refinery districts, where the quantities produced are relatively unimportant. About 35 percent of the kerosine production reported in 1951 was credited to the Texas Gulf Coast district, where the gain was nearly a quarter over the 1950 total. In the Indiana-Illinois-Kentucky group of States, which produce about one-fifth of the kerosine made in the country, the 1951 quantity was greater by 13 percent. The Louisiana Gulf Coast and the East Coast refinery districts are also important sources of kerosine, and there the outputs in 1951 were up 7 and 23 percent, respectively, over the 1950 quantities. In all these districts the higher production of kerosine in 1951 over 1950 was due largely to increased crude runs.

Domestic requirements for kerosine in 1951 were 5 percent above the 1950 total, which increase compares with a 15-percent gain in 1950 over 1949. Warmer weather in 1951 than in 1950, with a resultant leveled-off demand for kerosine as a heating fuel, was the chief factor causing the lower rate of gain in 1951. A cold January in 1951 brought about a 10-percent increase over 1950 in the kerosine market during the first quarter; however, with comparatively warmer weather from then until October, the need for kerosine for heating purposes was lowered, and as a result there was a 10-percent decline in the domestic demand in the third quarter of 1951 compared with the same 3 months of 1950. With a colder October and November in 1951, the gain in kerosine requirements for the closing quarter of the year rose to 7 percent over the final months of 1950.

Exports of kerosine plus shipments to the United States Territories rose sharply from 2,078,000 barrels in 1950 to 6,818,000 in 1951. The larger proportions went to the United Kingdom (1,514,000 barrels); India (1,243,000 barrels), Egypt (1,231,000 barrels); and Canada (598,000 barrels). The greatly expanded shipments of kerosine to the United Kingdom, Egypt, and India were evidently to replace supplies usually obtained from Iran, which were cut off with the closing of the Abadan refinery early in 1951, owing to the dispute with the British owners over nationalization of the Iranian petroleum industry.

Kerosine stocks at the end of 1951 were more than a quarter above those reported for 1950 and were also higher than the previous record volume held at the close of 1948. Kerosine stored at refineries increased from 11,315,000 barrels in the final month of 1950 to 12,858,000 in December 1951—a 14-percent gain—whereas quantities held at bulk terminals and in transit in pipelines rose sharply from 8,408,000 barrels in 1950 to 12,070,000 in 1951. Kerosine in storage at the end of 1951 represented a 47-day domestic supply at the January 1952 daily rate of demand compared to a 39-day supply at the close of 1950.

Increased stocks of kerosine were reported for all refinery districts at the end of 1951 compared with the 1950 totals, except three areas—Texas Inland, Rocky Mountain, and California— where the quantities stored are relatively unimportant. In the East Coast district, where kerosine stocks represent more than a third of the national total, there was an 8-percent increase in the inventory during 1951. There was a 22-percent increase in the kerosine held in the Indiana-Illinois-Kentucky district, whereas quantities were about a fifth of the country's inventory, while in the Texas Gulf Coast district, third in importance as a storage area for kerosine, the total increased by a half in 1951 over 1950.

Sales of kerosine for various uses, according to the annual survey made by the Bureau of Mines, showed an increase of 4 percent in 1951 over the 1950 demand, compared with a 15-percent gain in 1950 over 1949. The larger share (68 percent of the total in 1950 and 70 percent in 1951) of the kerosine is used in range burners for cooking and space heating. In 1950 the weather was considerably colder than in 1949, which was an important factor in the large increase in the kerosine demand. The fact that still greater requirements for heating, as measured by degree-days, were not repeated in 1951, was probably the more important reason for the lower percentage gain in kerosine requirements for the year. Kerosine sold for range burner fuel was up by approximately 8 percent in 1951 over 1950, compared with a 21-

percent gain in 1950 over the 1949 total. Some No. 1 fuel oil is also sold for range fuel and when this is added to the kerosine it shows a 9-percent increase in range-oil requirements for 1951 against a 21-percent increment in 1950 over 1949.

The amount of kerosine delivered for tractor fuel has steadily decreased in recent years, as gasoline and liquefied petroleum gases sold for this purpose have gained in importance. Sales of kerosine for tractor fuel declined by about 3 percent in 1951 compared with a shrinkage of 15 percent in 1950 from 1949 requirements. Kerosine sold for various miscellaneous uses, such as lamp fuel, orchard heating, weed burning, asphalt heating, dust control, etc., declined by 5 percent in 1951 against a 9-percent gain in 1950 over 1949.

Kerosine prices were held virtually stationary in 1951 under controls set up by the Office of Price Stabilization in contrast to many minor adjustments in 1950 compared with 1949. The only change in representative prices was for 41°–43° gravity water-white kerosine at Oklahoma refineries, where there was a reduction of a fractional cent per gallon in April 1951.

TABLE 67.—Sales of range oil in the United States, 1949–51, by States

[Thousands of barrels]

State	1949	1950	1951	
			Total	Percent of U. S. total
Massachusetts	13,486	13,505	13,479	13.1
New York	9,590	10,386	10,489	10.2
Illinois	5,002	6,184	6,936	6.7

[1] Manhattan and Queens.

Rail and truck shipments of kerosine from the California marketing area to other Western States totaled 20,000 barrels in 1951 compared with 25,000 in 1950. There have been no tanker shipments of kerosine from the west coast to the Atlantic seaboard in recent years. No kerosine was received on the west coast by overland routes in 1951, and the 1950 quantity was only 1,000 barrels.

Tanker and barge shipments of kerosine from gulf ports to the Atlantic seaboard increased only nominally—from 41,746,000 barrels in 1950 to 43,516,000 in 1951. The kerosine in this movement originating in Texas totaled 34,061,000 barrels in 1951, compared with 30,784,000 in 1950, whereas the quantity credited to Louisiana declined from 10,962,000 barrels in 1950 to 9,455,000 in 1951.

Tanker rates on kerosine shipped from gulf coast ports to New York fluctuated widely in 1951, with a sharp upward trend. A freight quotation of 88.2 cents a barrel at the end of December 1950 was raised to $1.084 in late January 1951. A slack-season "low" of 36.1 cents a barrel was posted on July 19; however, subsequent advances brought the rate to $1.084 a barrel at the end of November, the same level reached in January 1951. The average freight charge for kerosine for 1951 was 73.9 cents a barrel compared with 37.8 cents in 1950.

DISTILLATE FUEL OIL

Both the domestic demand and exports of distillate fuel oil showed important increases—14 percent and 79 percent, respectively, in 1951 over 1950; however, with a relatively large gain in production—19 percent—the supply was not only sufficient to satisfy these expanded markets, but an excess quantity was also diverted to storage. Additional supplies from "transfers"[6]—up 13 percent in 1951—and im-

[6] For definition, *see* text footnote 1 at the beginning of this chapter.

Digitized by Google

ports—down 26 percent—were relatively unimportant in volume. Ninety-nine percent of the distillate fuel oil came from new production in 1951, and about 93 percent of the total supply was diverted to the domestic market; 5 percent was exported, and the balance or 2 percent was added to storage. The production of distillate fuel oil in 1950 accounted for 98 percent of the supply, which in turn was supplemented by minor imports and "transfers" plus a small quantity taken from storage. The domestic demand accounted for 97 percent of the available quantity, and the balance was exported.

The domestic demand for distillate grades of fuel oil increased by 14 percent in 1951, compared with a 20-percent expansion in 1950 and a 3-percent decline reported in 1949. A cold January was the principal factor that brought about a 21-percent gain in the demand for light fuel oils in the first quarter of 1951 over the corresponding period of 1950. With a warmer second quarter in 1951 than in 1950, the indicated domestic demand showed only a nominal gain—11 percent—compared with a 30-percent increase in the same 3 months of 1950. The gain in domestic requirements of 4 percent in the third quarter and 13 percent in the final 3 months of 1951 were well below the percentage increases of 17 percent and 22 percent, respectively, reported for 1950 over the same periods of 1949.

Distillate-fuel-oil sales in 1951, according to the annual survey conducted by the Bureau of Mines, were 14 percent above the comparative 1950 totals. Deliveries to gas and electric power plants, the only sales that decreased, were down by 27 percent. The railroads in their shift to diesel equipment, strongly evident in recent years, bought 23 percent more light fuel oils, mostly diesel grades, in 1951 than in 1950; furthermore, the 1951 total for these distillates delivered to railroads was greater in volume than that for the residual grades for the first time. Sales of distillates, mostly diesel fuel, to vessels increased 12 percent over the 1950 total, in contrast to a 2-percent decline in 1950. Bunker deliveries of light fuel oils to vessels engaged in foreign trade increased by 45 percent from 5,229,000 barrels in 1950 to 7,580,000 in 1951, according to data compiled by the Bureau of the Census, United States Department of Commerce, whereas the indicated quantities of light fuel oils sold to vessels using coastal and inland waters declined from 7,643,000 barrels in 1950 to 6,813,000 in 1951.

Sales of distillate-grade fuel oils to gas and electric power plants dropped 27 percent in 1951, in contrast to a gain of 5 percent in 1950 over 1949. The drop was due largely to higher prices for fuel oil in 1951 and a resulting shift to other fuels and sources of energy, such as coal, natural gas, and hydro power. The total consumption of hydro power by electric power plants increased greatly in 1951 over 1950, according to records compiled by the Federal Power Commission. Smelters, mines, and manufacturing plants increased their purchases of distillate fuel oils by 13 percent in 1951 over 1950, compared with a 40-percent rise in 1950 over 1949. This lower rate of gain in 1951 in the requirements for light fuel oils by industrial plants, with the index of manufacturing up to 229 compared with 209 in 1950, according to the Federal Reserve Board, probably was due to increased fuel-oil prices in contrast to almost unchanged quotations for industrial grades of bituminous coal.

[1] Includes diesel fuel.

[2] Oil used to heat manufacturing plants is included under "Smelters, mines, and manufacturing industries," as the amount so used cannot be separated from the major portion used to generate power. Oil used to heat military and other Government buildings is included under "Heating oils."

Digitized by Google

In 1951, with a 10-percent increase in domestic burners over the 1950 number in use and with no change in the need for heating as measured by degree-days,[7] sales of light fuel oil (Grades 1–4) for space heating were 13 percent above the 1950 total. This gain in demand compares with a 16-percent increase in 1950, when burners in use were 15 percent above 1949 installations and the weather was 8 percent colder. The light fuel oil sold for heating accounted for approximately 56 percent of the total distillate-fuel-oil sales in both 1950 and 1951. No. 1 fuel oil delivered for range burner fuel showed a 10-percent increase in 1951 compared with a 20-percent gain in 1950 over the 1949 total.

Stepped-up military activities during the entire year are reflected in a 29-percent rise in the purchases of light fuel oils by the armed services, in contrast to a gain of 7 percent in 1950 over 1949 requirements. Oil companies use only a relatively small amount of distillate fuel oils in their various operations; however, with crude production up by 14 percent and a 13-percent gain in crude runs at refineries in 1951 compared with 1950, the quantity consumed increased by 55 percent, which compares with a 37-percent gain in 1950 over the 1949 total.

Major requirements for distillate fuel, including diesel oil and range oil, in recent years, are shown graphically in figure 10.

Closing of the Abadan refinery in Iran at the end of June 1951 and the necessity of finding other major sources of supply to satisfy world markets was probably the principal factor that caused United States exports and Territorial shipments of distillate fuel oil to almost double in volume in 1951 compared with 1950. The more important export items that increased were as follows: Canada, 5,401,000 barrels in 1950 and 6,547,000 in 1951; United Kingdom, 1,166,000 in 1950 and 3,410,000 in 1951; Mexico, 392,000 in 1950 and 1,165,000 in 1951; Sweden, 590,000 in 1950 and 1,123,000 in 1951; and the Philippines, 7,000 in 1950 and 379,000 in 1951. Although there were no exports of light fuel oil to the following countries in 1950, they were credited with relatively important quantities in 1951 as indicated: Netherlands Antilles, 1,749,000 barrels; Australia, 684,000; and Japan, 683,000. It is believed that the distillate shipped to the Netherlands Antilles was used for cracking stock in its petroleum refineries.

The 19-percent gain in the production of distillate fuel oil in 1951 can be attributed mainly to a 13-percent increase in crude runs to stills and secondly to a slightly higher yield—20 percent in 1951 against 19 percent in 1950. The light fuel oil produced at petroleum refineries in 1951 made up 99 percent of the total supply, compared with 98 percent in 1950.

There was a 23-percent gain in distillate-fuel-oil output in 1951 in both the Texas Gulf Coast area, where a quarter of the supply originates, and in the East Coast area, where a fifth of the total is produced. The Illinois-Indiana-Kentucky refinery district is another important source—about 16 percent of the national total—of light fuel oils, and there the output in 1951 was greater by 22 percent. Distillates made in the California refinery district account for about 11 percent of the annual production, and the quantity was up by 6 percent in 1951 over the 1950 total.

[7] The number of degree-days is the monthly sum of the differences between 65° and the daily mean temperature below 65°. Experience has shown that to heat buildings to a temperature of approximately 70° the amount of fuel or heat used per day is proportional to the number of degrees the average outside temperature falls below 65°.

Pipeline companies use some light crude petroleum as fuel, and the quantity is entered into the distillate fuel-oil account as "transfers." This item increased by 13 percent in 1951 compared to 1950 and represented less than 1 percent of the available light fuel oils.

Distillate-fuel-oil stocks held at the end of 1951 were 12 percent greater than those reported at the close of 1950. The 44,682,000 barrels stored at refineries on December 31, 1951, were 7 percent over the comparative quantity of 41,632,000 for 1950, whereas supplies reported at bulk terminals and in pipelines rose 19 percent from 30,316,000 barrels in 1950 to 36,040,000 in 1951. The light fuel oil in storage at the year end of 1951 represented a 40-day supply at the January 1952 daily rate of domestic demand, compared with a 39-day reserve at the close of 1950.

Most refinery districts showed important buildups in distillate-fuel-oil stocks during 1951. A third of the light-fuel-oil inventory was reported from the East Coast States, where the gain in the amount stored increased by 21 percent. There was an outstanding stock increase of 55 percent in the Indiana-Illinois-Kentucky district, where the total at the end of 1951 represented a fifth of the national reserve. Relatively important distillate stocks are credited to the Texas Gulf and California districts; however, the quantities declined by 2 and 36 percent, respectively, during 1951. This big shrinkage in West Coast distillate stocks in 1951 was largely the result of a tight supply in the area, as reported sales of light fuel oil were up by 12 percent, whereas the local production in 1951 was only 6 percent above the 1950 total. The 1951 year-end inventory for the Louisiana Gulf district, although not relatively important in volume, was 8 percent below the comparative quantity for 1950.

Rail and truck shipments of distillate from the west coast to other Western States continued a downward trend from 606,000 barrels in 1950 to 521,000 in 1951. Tanker shipments of distillate fuel oil from California to the east coast rose sharply from 66,000 barrels in 1949 to 1,554,000 in 1950 and then declined to only 34,000 in 1951. Distillate fuel oil shipped overland into the Pacific Coast marketing area increased from 1,095,000 barrels in 1950 to 1,669,000 in 1951.

Tanker and barge shipments of distillate fuel oil from the Gulf area to the Atlantic seaboard have increased steadily in recent years from 102,147,000 barrels in 1949 to 115,328,000 in 1950 and to 129,953,000 in 1951. The quantities shipped from Texas have expanded from 80,748,000 barrels in 1949 to 93,600,000 in 1950 and to 106,285,000 in 1951. Louisiana was credited with 21,399,000 barrels in 1949, 21,728,000 in 1950, and 23,668,000 in 1951.

Tanker rates for No. 2 distillate fuel oil from the Gulf coast to New York averaged 78.1 cents a barrel in 1951 compared with 39.5 cents in 1950. There were numerous changes in this freight charge in 1951 and a high of $1.138 a barrel was quoted in late January and again at the end of November. The 1951 low of 37.8 cents a barrel held for a few days in late July.

There were very few changes in representative distillate fuel oil wholesale prices during 1951, because of controls set up by the Office of Price Stabilization. In contrast to numerous adjustments in the price of No. 2 fuel oil at refineries in Oklahoma in 1950, there were only four minor changes in 1951, which resulted in a net reduction of less than a tenth of a cent a gallon during the 12 months. representative quotations for light fuel oils, including diesel grades remained at the same level throughout all of 1951.

Average retail fuel prices in a number of cities are published monthly by the Bureau of Labor Statistics, United States Department of Labor. The average price of No. 2 distillate fuel oil in New York City was 12.63 cents a gallon until May 1951, when it advanced to 12.75 cents, a quotation that held until November, when there was a slight reduction to an average of 12.71 cents a gallon. The average price for this grade of fuel oil for all of 1951 was 12.70 cents a gallon compared with 11.72 cents in 1950. The average price of No. 2 in Chicago was 13.63 cents a gallon from January through April 1951 and then dropped to 13.57 cents, a value that held for the remainder of the year. The average quotation was 13.59 cents a gallon in 1951 or slightly higher than the 1950 average of 12.64 cents.

RESIDUAL FUEL OIL

There was only a nominal increase—2 percent—in the domestic demand for residual fuel oil in 1951; however exports were up sharply, 79 percent compared with those of 1950. Production of heavy grades of fuel oil in 1951 was greater by 10 percent, and the transfers also gained 13 percent; consequently, there was a slight surplus in the supply, which was diverted to storage. Imports were lower by 1 percent compared with 1950 receipts from foreign sources. Demand and supply factors in 1951 differed from those prevailing in 1950, when both the domestic and export markets were considerably expanded; with virtually no increase in production, it was necessary to draw heavily on available stocks, even though imports and transfers were well above 1949 levels.

The domestic demand for residual fuel oil in 1951 rose to a new level for the second consecutive year. However, the gain in 1951 over 1950 (2 percent) was not as great as in 1950 when the increase over 1949 was 12 percent. There were substantial gains in all quarters of 1950 over 1949, but the percentage increase was less marked in the final 3 months. This tapering off continued into 1951 and resulted in an actual decline from 1950 of 7 percent in the third quarter compared to a 13-percent gain in the corresponding period of 1950 over 1949. The demand for heavy fuel oils was virtually the same in the closing quarters of both 1950 and 1951.

According to the annual canvass by the Bureau of Mines, sales of residual fuel oils showed a net overall increase of only 2 percent in 1951 over 1950, as deliveries to railroads and to the gas and electric public utilities were down sharply. The railroads, with their greatly expanded use of diesel equipment, bought 10 percent less heavy fuel oil in 1951 than in 1950, which compared with a 4-percent drop in 1950 from 1949 requirements. Suppliers reported a 15-percent gain in sales of heavy fuel oils to vessels in 1951 against a 4-percent increase in 1950 over 1949. Vessels engaged in foreign trade were credited with purchases of 63,809,000 barrels of heavy-fuel-oil bunkers at American ports in 1951 compared with 50,815,000 in 1950—a gain of 26 percent—according to the records of the Bureau of the Census, United States Department of Commerce. The indicated demand for heavy fuel oils by vessels using coastal and inland waters increased from 42,132,000 barrels in 1950 to 43,198,000 in 1951.

The fact that gas and electric power companies turned strongly to other sources of energy in 1951, owing largely to higher fuel-oil prices, was reflected in a 24-percent decline in their purchases of residual fuel oils. This sharp drop in heavy-fuel-oil sales to the utilities in 1951 contrasted with a substantial 16-percent gain in 1950 over the 1949 total. The index of industrial production, an indicator of the need for all fuels by heavy industries, rose from 209 in 1950 to 229 in 1951. Apparently higher prices for heavy fuel oil, in contrast to virtually stable prices for industrial grades of coal, were the important factor that limited sales of residual fuel oils to smelters, mines, and manufacturing plants to a 6-percent gain in 1951, compared with a 21-percent increase in 1950 over 1949 requirements.

Considerably colder weather and an 8-percent increase in commercial burners in use were factors that brought about a 20-percent expansion over 1949 in sales of heavy heating oils in 1950. There was a similar percentage gain in the number of commercial burners in use in 1951, but virtually no change in the coldness of the weather as measured by degree-days; consequently, sales of heavy grades of fuel oil for heating purposes showed only a nominal gain of 5 percent.

The Nation's military services increased purchases of Navy Grade and other heavy fuel oils by 34 percent in 1951, the first full year of operations since the beginning of hostilities in Korea. This stepped-up demand in 1951 compares with a 25-percent gain in military requirements for heavy fuel oils in 1950, when a tense international situation had prevailed only during the second half of the year.

The quantity of heavy fuel oil, including some crude petroleum and acid sludge, consumed by oil companies in their field and refinery operations has declined in recent years, as the petroleum industry has turned more and more to natural gas, refinery gas, and purchased

302512—54——66

Digitized by Google

electricity as sources of energy. Heavy grades of fuel oil used by oil companies increased less than 2 percent in 1951 over 1950 requirements, compared with a 3-percent gain in 1950 over 1949, and the quantities represented about a tenth of the residual-fuel-oil total for both years.

[1] Includes Navy grade and crude oil burned as fuel.
[2] Revised.

Sales of residual fuel oils in recent years are shown graphically in figure 11. All grades of heavy fuel oil and crude petroleum and acid sludge used as fuel are included.

Closing of the Abadan refinery in Iran in mid-1951, which necessitated a realinement of world fuel-oil-supply sources, was probably the principal factor that brought about a 79-percent increase in residual-fuel-oil exports and shipments to United States Territories in 1951 compared with 1950. The countries that received the largest shipments of heavy fuel oil in 1951 were as follows: Canada, 5,761,000 barrels; Japan, 3,991,000; Mexico, 2,328,000; Chile, 1,962,000; Australia, 1,803,000; Cuba, 1,229,000; and the United Kingdom, 1,109,000.

[1] Includes Navy grade and some crude oil burned as fuel.
[2] States are grouped according to petroleum-marketing districts rather than to conventional geographic regions.

Digitized by Google

A 10-percent gain in the production of residual fuel oil in 1951 compared with 1950 was definitely due to higher crude runs at refineries, as the percentage yield dropped fractionally. Residual fuel oils from new production made up 79 percent of the supply in 1951 compared with 75 percent in 1950. All refinery districts reported higher outputs of heavy fuel oil in 1951, except the Arkansas-Louisiana Inland area, where the quantity produced is relatively unimportant. About 30 percent of the residual fuel oils were produced in the California district, where a 13-percent gain was associated with both higher refinery runs and an increased percentage yield. The East Coast and the Indiana-Illinois-Kentucky refinery districts produced important quantities of heavy fuel oils, and gains in those areas in 1951 of 11 and 10 percent, respectively, were the result of stepped-up crude runs, as percentage yields were down slightly. A higher crude throughput coupled with a lower yield also prevailed in the Texas Gulf district, which produced a fifth of all residuals in 1951 or a quantity 9 percent above the 1950 total. The volume of heavy fuel oils coming from the other refinery districts was relatively small.

Heavy crude oil burned as fuel on oil-company leases and in industrial plants is entered into the residual-fuel-oil account as transfers, and the quantity so used each year represents about 1 percent of the supply from all sources. About one-third of the transfers is reported from the California refinery district, whereas the balance is credited to the other refinery areas of the country, not including the East Coast and Appalachian districts. Transfers increased 13 percent in 1951 over the 1950 total, with a 14-percent gain in the West Coast district and a 12-percent gain for the area east of California.

Imports of heavy fuel oil account for about a fifth of the total supply from all sources. There was an unusually large increase—60 percent—in the quantity received from foreign sources in 1950 over the 1949 total, but this was not repeated in 1951, as there was a 1-percent decline in the volume, probably due to closing of the Abadan refinery in Iran and the resulting readjustment of world supply sources. In 1951, as in 1950, most imported residual fuel oil came from Netherland Antilles—95,057,000 barrels—with smaller amounts from Venezuela—24,611,000 barrels—and from Trinidad and Tobago—1,835,000 barrels.

Heavy-fuel-oil stocks at the close of 1951 showed a net increase of only 3 percent over the 1950 total; however, there were some rather important changes in the different refinery districts. A heavy decrease in residual-fuel-oil stocks reported for the California refinery area in 1950 was repeated in 1951, but in a lesser degree. The shrinkage there of about 50 percent in 1950 from 1949 was due to large shipments of heavy fuel oil to the east coast; and a further 22-percent decline in 1951 was undoubtedly associated with heavy exports, which about doubled during the year, and greater military requirements. About a quarter of the heavy fuel oils are stored in the East Coast district, where there was only a nominal increase—5 percent—in 1951 over the 1950 year-end quantity. Residual stocks increased in 1951 by 58 percent in the Indiana-Illinois-Kentucky district and by 19 percent in the Texas Gulf area, other important storage areas.

Residual-fuel-oil inventories at petroleum refineries increased 7 percent from 31,003,000 barrels at the close of 1950 to 33,035,000 a year later, whereas quantities reported at bulk terminals and in pipelines

Digitized by Google

decreased 8 percent from 9,747,000 barrels in 1950 to 8,944,000 in 1951. The refinery stocks made up 76 percent of the total heavy-fuel-oil stocks in 1950 and 79 percent at the end of 1951, and the bulk and pipeline share declined proportionately during the same interval. Year-end stocks of heavy fuel oils for both 1950 and 1951 represented a 23-day supply at the following January daily rate of domestic demand.

There was a small in-and-out movement of residual fuel oils by rail and truck between the Pacific Coast marketing area and other Western States. Shipments out of California were 467,000 barrels in 1951 compared with 362,000 in 1950, whereas receipts in the Pacific Coast area from other States totaled 370,000 barrels in 1950 and 356,000 in 1951.

Tanker shipments of heavy fuel oils from California to the east coast, which reached a record volume of 15,429,000 barrels in 1950, dwindled to a mere 140,000 barrels in 1951.

Barge and tanker shipments of residual fuel oil from the gulf coast to the Atlantic seaboard of 60,379,000 barrels in 1951 were only slightly above the 1950 total of 59,292,000 barrels. The quantity originating n Te xas declined from 53,102,000 barrels in 1950 to 52,868,000 in 1951, whereas that from Louisiana showed a substantial gain (21 percent) from 6,190,000 barrels in 1950 to 7,511,000 in 1951.

The tanker rate for Bunker "C" fuel oil on the gulf coast-New York run more than doubled from an average of 41.1 cents a barrel in 1950 to 87.4 cents in 1951. The freight charge on this heavy grade of fuel oil rose to $1.315 a barrel in late January 1951, in mid-February, and again just after the middle of December. The 1951 low quotation of 41.7 cents a barrel held for a week in the middle of May.

An upward trend in average prices for the year for residual fuel oils, evident in 1950, was continued in 1951, although the actual number of changes were far less numerous in the later year. An average quotation for No. 6 grade at refineries in Oklahoma of $1.88 a barrel dating from December 19, 1950, was reduced to an average of $1.80 on May 1, 1951, and to $1.78 on May 4. There was a third reduction to $1.73 a barrel on October 9, however, the average value for all of 1951 was $1.80 a barrel compared with $1.64 in 1950. An average price of $3.10 a barrel for No. 5 fuel oil at New York Harbor, dating from late October 1950, held until June 4, 1951, when it was raised to $3.25 and then to $3.40 on June 6, at which level it remained unchanged for the balance of the year. The average quotation for this No. 5 grade advanced from $2.79 in 1950 to $3.27 in 1951.

A quotation of $2.15 a barrel for Bunker "C" for ships' bunkers at New York Harbor posted in November 1950 was raised to $2.30 and then to $2.45 a barrel in early June 1951, where it remained unchanged, resulting in an average price of $2.32 for all of 1951 compared with $2.09 a barrel in 1950. A price of $1.85 a barrel for Bunker "C" at New Orleans, announced in July 1950, held throughout 1951. Likewise, the quotation for Bunker "C" at San Pedro, Calif., of $1.78 a barrel dating from mid-December 1950 was maintained throughout 1951.

Retail prices of various fuels in a number of cities are published monthly by the Bureau of Labor Statistics, United States Department of Labor. These releases show that the price for No. 6 Grade in New York in dumps of 100 gallons or more rose gradually from an average of 6.14 cents a gallon in January 1951 to 6.92 cents in June

San Pedro	1.78	1.78	1.78	1.78	1.78	1.78	1.78	1.78	1.78	1.78	1.78	1.78	1.78

and that the quotation remained at that level for the balance of the year. The average price for this heavy fuel oil at New York for all of 1951 was 6.63 cents a gallon compared with 5.93 cents in 1950. No. 5 fuel oil at Chicago, priced at 10 cents a gallon in January 1951, advanced to an average of 10.13 cents in May, and then dropped back to 10 cents a gallon for the balance of 1951. The average quotation for 1951 was 10.09 cents a gallon against 9.27 cents in 1950.

LUBRICANTS

The refinery production of lubricating oils and greases increased from 51.7 million barrels in 1950 to 61.5 million in 1951. Of the total increase of 9.8 million barrels, 4.1 million was in the Texas Gulf district, 2.0 million in the Louisiana Gulf district, 1.2 million in the Indiana-Illinois district, 1.0 million barrels in the East Coast district, and 0.6 million in the California district. In 1951 the percentage of total production by districts was 33.6 percent in the Texas Gulf, 18.3 percent in the East Coast, 10.6 percent in the Louisiana Gulf, 9.8 percent in the Indiana-Illinois district, 8.8 percent in the Appalachian, 7.7 percent in the Oklahoma-Kansas, 7.6 percent in California, and 3.6 percent in all other districts. Production exceeded demand, as 1.8 million barrels was added to stocks.

The total demand for lubricants rose to 59.7 million barrels in 1951, a gain of 6.6 million. Exports increased 3.2 million barrels to 17.4 million, and the domestic demand of 42.3 million barrels showed a gain of 3.5 million or 9 percent. No current figures are available on the relative demand for industrial and automotive uses. The automotive demand has been affected by the growing practice of reclaiming lubricants for reuse and by less frequent changes in oil.

Table 78 shows the prices of representative grades of lubricants for 1950 and 1951.

LIQUEFIED GASES

The sale of liquefied gases for fuel, chemical, and motor fuel uses has expanded rapidly and now ranks after kerosine in the volume of total demand. Liquefied gases are derived from two sources—production from liquids recovered from natural gas at natural gasoline and allied plants and at refineries from the treatment of still gas.

The production from oil refineries rose from 29.1 million barrels in 1950 to 33.0 million in 1951. The transfers of production from natural-gasoline plants increased from 58.2 million barrels in 1950 to 72.4 million in 1951. The transfers represented 66.7 percent of the total supply in 1950 and 68.7 percent in 1951. The output at refineries was 33.3 percent of the total in 1950 and 31.3 percent in 1951. The product from the two sources cannot be distinguished when sold to the consumer or exported.

The total demand for liquefied gases rose from 87.1 million barrels in 1950 to 105.4 million in 1951, a gain of 18.3 million barrels or 21 percent. Exports increased from 1.6 million barrels to 2.1 million, and domestic demand rose from 85.5 million to 103.4 million, a gain of 17.8 million barrels or 20.9 percent. The details of the sales of liquefied gases by types and uses can be found in the Natural-Gas Liquids Chapter.

OTHER PRODUCTS

Wax.—The total refinery production of wax increased from 4,462,000 barrels in 1950 to 4,814,000 in 1951 (converted at the rate of 280 pounds to the barrel).

Out of the total increase in production of 352,000 barrels in 1951, 134,000 was in the East Coast district, 104,000 in the Texas Gulf, 84,000 in the Oklahoma-Kansas district, and 42,000 in the Appalachian district; Louisiana Gulf Coast production declined 21,000 barrels. The East Coast district produced 33.1 percent of the total in 1950 and 33.5 percent in 1951.

In 1951, 219,000 barrels was added to stocks and total demand was 4,595,000 barrels, including exports of 1,351,000 and domestic demand of 3,244,000 barrels. Compared with 1950, exports increased 158,000 barrels and domestic demand only 6,000 barrels.

Coke.—The production of petroleum coke continued to increase in 1951, amounting to 19.0 million barrels compared with 17.2 million in 1950 (converted at the rate of 5 barrels to the short ton). The largest increases in production were 0.7 million barrels in the Indiana-Illinois district and 0.5 million in the Arkansas-Louisiana Inland

Digitized by Google

district. The Indiana-Illinois district was the largest producer, accounting for 45.8 percent of the total in 1950 and 45.3 percent in 1951.

The total demand for petroleum coke increased from 17.5 million barrels in 1950 to 18.9 million in 1951. Exports increased from 2.5 million barrels to 4.5 million, whereas domestic demand declined from 15.0 million barrels to 14.4 million in 1951.

[1] Conversion factor: 5 barrels to the short ton.
[2] Preliminary figures.
[3] Figures not available.

Asphalt and Road Oil.—The total demand for petroleum asphalt increased 7.7 million barrels to 67.3 million in 1951 (converted at the rate of 5.5 barrels to the short ton). Domestic demand amounted to 66.2 million barrels, a gain of 7.5 million or almost 13 percent. The domestic demand for road oil amounted to 6.1 million barrels in 1951, a decline of 0.8 million or about 12 percent. The details as to sales of asphalt and types of product are contained in the Asphalt chapter of the Minerals Yearbook.

Still Gas.—The production of still gas increased from 83.7 million barrels in 1950 to 96.3 million in 1951—a gain of about 15 percent. The reported figure in cubic feet increased from 301 billion in 1950 to 347 billion in 1951. The conversion from cubic feet to barrels is in terms of the crude-oil equivalent to balance the refinery input and output, rather than on the basis of heating value. The major part of the still gas is consumed as fuel at the refineries.

Miscellaneous Oils.—The production of miscellaneous products amounted to 7,201,000 barrels in 1951.

INTERCOASTAL SHIPMENTS [8]

Shipments of mineral oils, crude and refined, from gulf coast ports to east coast ports were 12.5 percent larger in 1951 than 1950. Crude petroleum was the largest single item in 1951; it constituted 31 percent of the total shipments. A 19-percent increase in crude coastwise shipments brought crude petroleum from second rank in 1950 to first place in 1951. Gasoline, which held first place in 1950 with nearly 30 percent of the total, in spite of a quantitative increase from 1950 to 1951, fell to second place in 1951 with a little less than 29 percent of intercoastal shipments.

The increased shipments of crude petroleum from the gulf coast to the east coast may be ascribed to larger refinery runs and to a comparatively small increase in receipts of foreign crude at east coast refineries. The 10-percent increase in shipments of refined products from the gulf coast to the east coast was due to a demand for petroleum products even greater than the enlarged output of east coast refineries could supply and to a small decline in imports of refined products.

Digitized by Google

Intercoastal shipments of refined oils from California to east coast ports, which began in 1946 with 740,000 barrels and climbed by 1950 to 23,450,000 barrels, amounted in 1951 to 577,000 barrels. No gasoline was included in the 1951 total, and 58 percent of the entire shipments consisted of lubricating oil.

FOREIGN TRADE [9]

For a number of years it has been the established custom of the Bureau of Mines to relate all its published statistics of petroleum imports and exports to continental United States. Accordingly, statistics of petroleum imports published in table 85 are net imports of crude and refined petroleum into continental United States and do not include such imports into the Territories. Correspondingly, statistics of petroleum exports used in table 87 include not only exports to foreign countries but also shipments from continental United States to the Territories, less exports from the Territories. The Bureau of Mines has published in table 85 figures obtained directly from the petroleum refiners covering their direct receipts of foreign crude. Such figures harmonize with the figures reported by the refineries for stocks and for runs to stills. Where it is desired to show the origins of the imports and the destinations of the exports, recourse is had to the statistics published by the Bureau of the Census, Department of Commerce.

Imports.—Imports of mineral oils, crude and refined, into continental United States decreased 1 percent from 1950 to 1951. They constituted nearly 13 percent of the total new supply in continental United States in 1950 and 11 percent in 1951. Total imports exceeded total exports by 179 percent in 1950 and 99 percent in 1951.

Crude petroleum, distillate fuel oil, and residual fuel oil together made up 97 percent of the total mineral-oil imports into continental United States both in 1950 and 1951. Crude petroleum alone constitutes 57 percent of the total in 1950 and 58 percent in 1951.

Venezuela supplied 42 percent of the total petroleum imports into continental United States and the Territories in 1950 and in 1951, the Netherland Antilles 32 percent in 1950 and 31 percent in 1951, Mexico nearly 6 percent both in 1950 and in 1951, and Colombia 5 percent in both years. A newer source of supply, the countries bordering the Persian Gulf, furnished nearly 14 percent of the total in both 1950 and 1951.

Of the crude petroleum imported in 1950, Venezuela provided 62 percent. Colombia 9 percent, Mexico nearly 6 percent, and Kuwait and Saudi Arabia 23 percent. In 1951 Venezuela provided 60 percent, Colombia 9 percent, Mexico 7 percent, Kuwait and Saudi Arabia 21 percent, and British Malaya 2 percent.

Of the residual fuel oil imported into continental United States and the Territories the Netherland Antilles supplied 79 percent in 1950, Venezuela 18 percent and other Caribbean countries 2 percent. Of the corresponding imports in 1951, the Netherland Antilles sent 78 percent, Venezuela 20 percent, and other Caribbean countries less than 2 percent.

TABLE 86.—Crude petroleum and major petroleum products imported for consumption into the United States, 1950–51, by countries, in thousands of barrels [1]—Continued

[U. S. Department of Commerce]

Country	Crude petroleum	Motor fuel [2]	Kerosine	Distillate oil [3]	Residual oil [4]	Unfinished oil	Total
1951—Continued							
Asia:							
British Malaya	3,543			1			3,544
Indonesia	(5)						(5)
Kuwait	21,648						21,648
Saudi Arabia	16,161			960			17,121
State of Bahrein			(5)	419	104		523
Total	41,352		(5)	1,380	104		42,836
Africa:							
French Morocco			(5)				
French West Africa			(5)				
Total			(5)				
Grand total	177,474	2,113	(5)	2,908	121,824	5,265	309,584
Imports into United States Territories and possessions from foreign countries:							
Alaska		(5)					(5)
Hawaii				1,138			1,138
Puerto Rico		15			2,803		2,818
Total		15		1,138	2,803		3,956
Total net imports into continental United States	177,474	2,098	(5)	1,770	119,021	5,265	305,628

[1] Compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.
[2] Includes naphtha and benzol.
[3] Includes quantities imported free of duty for supply of vessels and aircraft.
[4] Includes quantities imported free of duty for manufacture in bond and export, and for supply of vessels and aircraft.
[5] Less than 500 barrels.
[6] Revised figure.

Exports.—Continental United States, formerly a net exporter of mineral oils, continued in 1951 to be a net importer. The excess of all petroleum imports over all petroleum exports—over 116 million barrels in 1949—increased in 1950 to nearly 199 million barrels but declined to 153 million barrels in 1951, as United States exports of refined products increased 64.5 percent to meet the abnormal foreign demand occasioned by the shutdown of the Abadan refinery and as Caribbean exports of refined oils were diverted from the United States to Europe.

Crude petroleum, in contrast to most refined products, showed an excess of imports of nearly 143 million barrels in 1950 and of 150 million barrels in 1951. At the same time, imports of residual fuel oil exceeded exports of this product by nearly 104 million barrels in 1950 and by more than 90 million barrels in 1951. With regard to other refined petroleum products, exports exceeded imports by nearly 48 million barrels in 1950 and nearly 87 million barrels in 1951.

Exports of crude petroleum decreased nearly 18 percent from 1950 to 1951. Of the 1951 exports, 74 percent went to Canada, 8 percent to Japan, nearly 8 percent to Cuba, not quite 5 percent to Argentina, and the remaining 5 percent to various European countries. None was shipped to the United States Territories or possessions.

Digitized by Google

Exports and Territorial shipments of motor fuel from continental United States increased 62 percent from 1950 to 1951. The principal gains were in exports to Europe, notably to the United Kingdom, Africa, especially the Union of South Africa, Australia and New Zealand, and in shipments to the United States Territories and possessions. The increased exports of motor fuel from the United States to the United Kingdom and to other members of the sterling area, even at the cost of greater dollar expenditures by the purchasers, largely reflected the abrupt closure in July 1951 of the Abadan refinery, which had previously supplied these areas.

Exports and Territorial shipments of kerosine increased nearly 231 percent from 1950 to 1951. The most striking increases were in exports to the United Kingdom, India, Egypt, and Australia and in shipments to Territories and possessions other than Alaska and Hawaii.

Exports and Territorial shipments of distillate fuel oil from continental United States were 79 percent larger in 1951 than in 1950. Large gains were made in exports to Canada, the Netherland Antilles, Sweden, the United Kingdom, Japan, the Philippines, Australia, and New Zealand and in shipments to the United States Territories and possessions.

Exports and Territorial shipments of residual fuel oil from continental United States increased 79 percent from 1950 to 1951. Larger exports were made to North American destinations, notably to Canada, Cuba, and Mexico. Exports to South America were only slightly less in 1951 than in 1950. Exports of residual fuel oil to Europe were 11 times as large in 1951 as in 1950. Chief destinations in 1951 were the United Kingdom, Norway, Germany, and Sweden, all of which in 1950 were relatively small importers of residual fuel oil. The most striking increase was in exports to Asia, notably to Japan, British Malaya, and the Philippines. Australia and New Zealand, which took no residual fuel oil from the United States in 1950, received more than 2 million barrels of residual fuel oil from this source in 1951. Territorial shipments of residual fuel oil to Alaska and Hawaii were increased 12 percent from 1950 to 1951.

Exports and Territorial shipments of lubricating oils from continental United States increased 22 percent from 1950 to 1951, in spite of decreases in exports to Europe, Asia, and Oceania, and smaller decreases in exports to Africa. The gain was almost entirely in exports to destinations which may not be disclosed for security reasons.

Total net shipments from continental United States	28,603	40,171	6,873	22,639	28,999	16,794	1,349	145,428

[1] Compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

[2] Changes in Minerals Yearbook, 1950, pp. 997–998, are as follows: Wax exported to Hong Kong, 44; total Asia, 89; total, 1,192; grand total, 1,192.

[3] Country and continent totals exclude, but the grand totals include 10,071 thousand barrels of motor fuel and 6,313 thousand barrels of lubricating oils, for which country breakdown may not be published for security reasons.

[4] Less than 500 barrels.

[5] Figures represent shipments from refining companies for export to Alaska and Hawaii through Pacific coast ports, as reported to Bureau of Mines by shippers.

[6] Figures represent shipments to all other possessions and areas administered by the United States as reported by the U. S. Department of Commerce, January–July; and estimates by the Bureau of Mines, August–December.

WORLD PRODUCTION

Despite elimination of Iran from the list of producing countries in the middle of 1951, the loss in output was made up by other countries. The world petroleum production stood at an alltime high in 1951. It increased nearly 13 percent—from 10,419,000 barrels daily in 1950 to 11,734,000 barrels daily in 1951.

The chief gains, both quantitative and proportional, were in the Western Hemisphere. The United States contributed most, with an increase of nearly 14 percent—from 5,407,000 barrels daily in 1950 to 6,149,000 in 1951. As in 1950, it supplied 52 percent of the world total in 1951. Venezuela showed the next-largest quantitative increase from 1950 to 1951. Increased drilling, new pipelines, and enlarged refining capacity stimulated petroleum production.

The most striking increase in petroleum production (66 percent) occurred in Canada. This increase may be attributed chiefly to three new oil fields: (1) The Williston Basin in southwestern Manitoba; (2) northwestern Alberta to Fort St. John in northeastern British Columbia; and (3) Alberta southeast of Edmonton. The opening of the Interprovincial Pipeline gave these western fields access to markets in eastern Canada.

Mexico raised its petroleum production 7 percent from 1950 to 1951. Five new producing fields were added in 1951.

In the Middle East, a 47-percent decrease in the petroleum production of Iran was more than compensated by rising output in Kuwait and Saudi Arabia. In Iraq a new 16-inch pipeline from Kirkuk to the Mediterranean supplemented the existing two 12-inch lines to Tripoli and Haifa; and a new 80-mile pipeline to the Persian Gulf gave an outlet to crude petroleum from the new oil field at Zubair. New drilling increased the production of the Dukhan field in Qatar 47 percent from 1950 to 1951.

In Europe the noteworthy increase in petroleum production was in Western Germany, where the Emsland district was still the most important producer.

Phosphate Rock

By Bertrand L. Johnson and G. E. Tucker

GENERAL SUMMARY

MINE production of phosphate rock in the United States in 1951 (10.8 million long tons) was approximately one-third of a million tons less than the record high of 1950 (11.1 million tons). Decreases were shown in Florida and Tennessee; an increase of 9 percent was reported, however, in the Western States total. Total stocks in producers' hands decreased.

Sales increased, rising from 10.3 million long tons in 1950 to 11.1 million tons in 1951 (a record high); part of this came from stocks. (See fig. 1.) There were large increases in sales in Florida and the Western States, while those of Tennessee rock increased only slightly. The total value of the phosphate rock sold or used in 1951 rose to $66.2 million, a record high value and a little more than 7 million dollars above the 1950 level. The P_2O_5 content of the phosphate rock sold or used in 1951 increased to a new record high of 3.6 million long

[9] Includes brown-rock matrix of sinter grade and sintered brown rock.

tons from 3.3 million tons in 1950. Imports increased both in quantity and value in 1951. Exports, however, as reported by producers to the Bureau of Mines, were below 1950 in quantity, but above in value. Apparent consumption of phosphate rock in 1951 rose to a record high of 9.5 million long tons.

DOMESTIC PRODUCTION

Mine production of phosphate rock in the United States in 1951 (10,775,000 long tons) was 339,000 tons below the record high of 1950 (11,114,000 tons). Decreases occurred in Florida and Tennessee, more than offsetting a 9-percent rise in the Western States total.

[1] Includes some brown-rock matrix of sinter grade, a small quantity of apatite from Virginia in 1942–47 and 1949, and in 1942–43 some matrix of washer grade.

SALES

A record high of 11,095,000 long tons of domestic phosphate rock sold or used was reached in 1951, an increase over 1950 of 842,000 tons. The total value of $66,158,000 was likewise a record high.

REVIEW BY STATES

SOUTHERN STATES

Florida.—The upward trend in the marketed production (sold or used by producers) of Florida phosphate rock continued in 1951; a record total of 8,497,000 long tons valued at $50,263,000 was attained. By far the greater part of the production came from the land-pebble field, with relatively small quantities of hard-rock phosphate and soft phosphate (waste-pond phosphates from the hard-rock field) being produced. The sales of soft rock continued to be somewhat larger than those of hard rock.

TABLE 5.—Florida phosphate rock sold or used by producers, 1947–51, by kinds

Year	Hard rock			Soft rock [1]		
	Long tons	Value at mines		Long tons	Value at mines

1951	8,329,033	49,185,072	5.91	8,496,831	50,262,562	5.92

[1] Includes material from waste-pond operations.

In the land-pebble phosphate-rock field, the American Agricultural Chemical Corp. operated its No. 3 and No. 12 mines and washers, its recovery unit, and its drying plant at Pierce in 1951. The American Cyanamid Co. operated both its Saddle Creek and Sydney mines and washers and dried the phosphate rock produced at its Brewster drying plant. A description of the Sydney plant was published early in 1951.[1] This company has reclaimed for grazing purposes a large worked-out tract of land scarred by the phosphate-mining operations by smoothing off the area to form low, rolling hills and then planting indigo and grass. The Armour Fertilizer Works reported that there were no mining operations in 1951 at its Florida property near Bartow. The capacity of its triple superphosphate plant, however, was being doubled. The Coronet Phosphate Co. operated its Eleanor and Tenoroc mines and washers and its Coronet drier during the year. The Davison Chemical Corp. mined and washed phosphate rock at

[1] Lenhart, W. B., Latest Recovery Methods Highlight Florida Phosphate Plant: Rock Products, vol. 54, No. 3, March 1951, pp. 74–81.

Digitized by Google

its Bonny Lake and Pauway No. 4 mines and washers and dried the washed phosphate rock at its Ridgewood drying plant. The International Minerals & Chemical Corp. operated its Achan, Peace Valley, and Noralyn mines and washers and its Mulberry and Noralyn driers in 1951. The new company office building and warehouse and service center at Bartow were completed in 1951. Three new dragline excavators were said to have been installed in 1951, and building construction was begun on a new phosphate chemical plant near Mulberry to produce triple superphosphate, defluorinated phosphate, and uranium compounds. Automatic controls in the pumping and flotation operations of this company were described in papers given at the St. Louis meeting of the American Institute of Mining and Metallurgical Engineers, February 19 to 22, 1951.[2] Swift & Co. operated its Swift No. 5 and Swift No. 6 mines and washers, drying the phosphate rock at its Agricola drying plant. The Virginia-Carolina Chemical Corp. operated its Homine and Clear Springs mines and washers and mined feed from the Phosmico debris dump. The Phosmico and Nichols drying plants were in operation. Some phosphate rock was calcined.

In the hard-rock phosphate field the Kibler-Camp Phosphate Enterprise continued to operate its Section 12 mine, washer, and drying plant. Shipments were entirely for domestic consumption.

Several soft-rock phosphate-mining companies were in operation in 1951, mining the fine-grained phosphatic residues in the old waste-pond dumps near Hernando, High Springs, and Dunnellon in the hard-rock phosphate field. Part of this material was sold for domestic use as a phosphatic fertilizer for direct application to the soil, some for stock and poultry feed, and a small quantity for fertilizer filler. Some was exported to Canada.

The use of isopachous and related maps in studies of phosphate rock in the Florida land-pebble area was described in a paper published late in 1951.[3]

Tennessee.—Tennessee remained the second largest phosphate-rock-producing State. The quantity of phosphate rock sold or used by Tennessee producers in 1951 was 35,419 long tons greater than in 1950, increasing from 1,384,000 tons in that year to 1,420,000 tons in 1951. The total value in 1951 was $576,000 above that of 1950 and reached $10,605,000.

A short summary of the history of phosphate-rock mining in Tennessee was included in a general review of the history and development of phosphate-rock mining published in 1951.[4]

In 1951 the International Minerals & Chemical Corp. acquired the Hoover & Mason Phosphate Co., operating in the brown-rock phosphate district, Mount Pleasant, Tenn. It also purchased the Thomson Phosphate Co., of Chicago, Ill., a sales and distributing organization of ground phosphate rock to dealers and farmers for direct application to the soil. Thomson's source of raw material had been the International Minerals & Chemical Corp. This latter company operated mines and washers in 1951 at Mount Pleasant and Wales, in the Tennessee brown-rock-phosphate field.

The Tennessee Valley Authority continued mining and processing activities in Tennessee and technological operations at its chemical plant at Muscle Shoals, Ala., in 1951. According to the Authority's annual report for the fiscal year ended June 30, 1951, 426,400 tons of phosphate matrix was mined from its Tennessee properties. These properties normally provide 60 percent of the raw phosphate used by TVA, the remainder being chiefly high-grade Florida land pebble. TVA was prospecting in the Florida hard-rock phosphate field for an additional supply.

During fiscal 1951 TVA produced over 33,500 tons of elemental phosphorus from its electric furnaces. Phosphorus-bearing byproducts were 3,100 tons of potash-phosphate ash fertilizer and 9,700 tons of ferrophosphorus. There was produced about 142,900 tons of concentrated superphosphate, making a total of 1,334,000 tons since production began. TVA's production of calcium metaphosphate (60–62 percent P_2O_5) in the fiscal year ended June 30, 1951, was 31,300 tons, of which about 24,000 tons was sold and about 6,500 used for test demonstrations. A two-furnace demonstration plant for the production of fused tricalcium phosphate (26–30 percent P_2O_5) was in operation at Columbia, Tenn. Nearly 17,500 tons was produced in the fiscal year ended June 30, 1951. Pilot-plant studies were continued by TVA on two processes for the production of nitraphosphate fertilizer in which nitric acid is used in the treatment of phosphate rock.

The Monsanto Chemical Co., St. Louis, Mo., and the Victor Chemical Works, Chicago, Ill., continued to produce elemental phosphorus at their plants at Monsanto and Mount Pleasant, respectively, in the Tennessee brown-rock phosphate field.

One of the older phosphate-rock producers, the Federal Chemical Co., with properties in the Mount Pleasant, Tenn., district, did not operate during 1951.

WESTERN STATES

Total marketed production (sold or used by producers) of Western States phosphate rock rose from 783,000 long tons in 1950 to 1,178,000 tons in 1951. The total value also increased, rising from $3,622,000 in 1950 to $5,291,000 in 1951. Phosphate rock was produced and sold in all four States of the western field in 1951—Idaho, Montana, Utah, and Wyoming. Idaho led in sales, with Montana second and Wyoming third. (*See* fig. 2.)

[1] Idaho includes Utah in 1947–48 and 1950, and Wyoming in 1949–50.

Idaho.—Idaho retained its position as the leading phosphate-rock producer of the Western States in 1951, increasing its output considerably to 694,000 long tons, with a value of $1,748,000. The average value per ton was low ($2.52) because of the large quantities of low-grade phosphate produced for smelting in elemental phosphorus electric furnaces. A 1951 article describes the phosphate rock industry of Idaho.[5]

Three companies reported producing phosphate rock in Idaho in 1951. The Simplot Fertilizer Co., Pocatello, Idaho, continued its open-pit operations at the Gay mine on the Fort Hall Indian Reservation, Bingham County, about 16 miles east of Fort Hall. The high-grade phosphate rock from this property is used by that company for the production of superphosphate at Pocatello. The low-grade phosphatic shales from this operation go to the Westvaco elemental phosphorus electric furnaces at Pocatello. The Anaconda Copper Mining Co. operated its No. 3 phosphate rock mine at Conda, Caribou County, Idaho, processing the phosphate rock at the company plant at Anaconda, Mont., largely to triple superphosphate through the use of its byproduct sulfuric acid. The San Francisco Chemical Co., Montpelier, Idaho, reopened and operated its Waterloo mine on Waterloo Hill 5 miles east of Montpelier in 1951.

Fifteen phosphate leases, originally assigned to the J. R. Simplot Co., were reassigned in 1951, by the Secretary of the Interior, to the Monsanto Chemical Co., St. Louis, Mo. Monsanto purchased the leases from Simplot and was expected to smelt the phosphate rock produced from these leases in an elemental phosphorus electric furnace plant to be built near Soda Springs, Idaho.

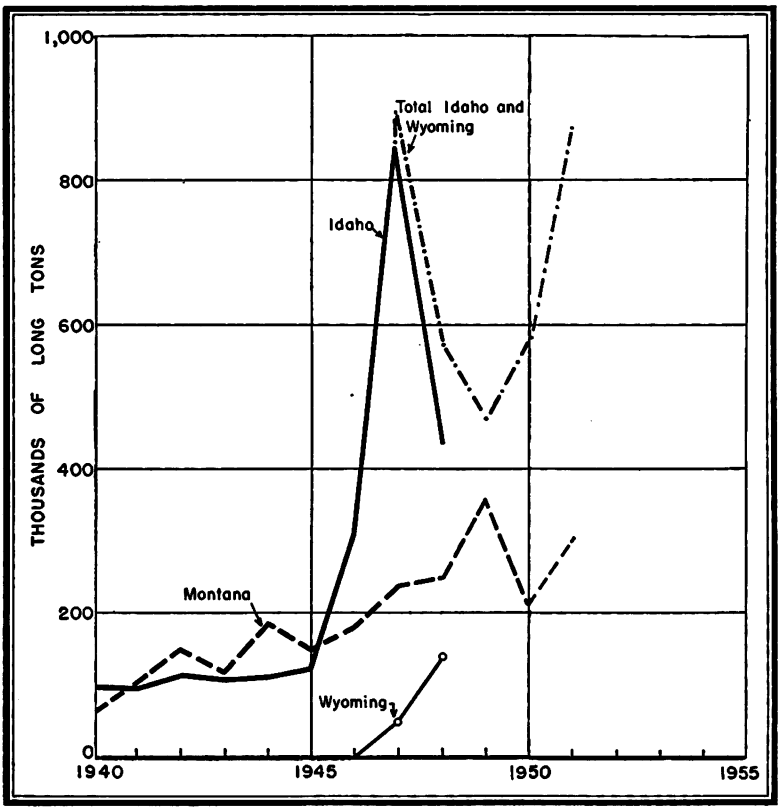

FIGURE 2.—Western States phosphate rock sold or used by producers, 1940–51.

Montana.—Marketed production of Montana phosphate rock in 1951 partly recovered from the sharp decline from 1949 to 1950, rising to 305,000 long tons, valued at $2,353,000 from 210,000 tons, valued at $1,497,000 in 1950.

The Montana Phosphate Products Co., Trail, British Columbia, operated its Anderson, Graveley, and Luke mines, all in the Garrison district, Powell County, in 1951. The Luke mine was closed temporarily part of the year. All phosphate rock produced from these mines was exported to the plant of the parent company, Consolidated Mining & Smelting Co., of Canada, Ltd., at Trail, British Columbia. Mining operations were also carried on by George Relyea at the Relyea phosphate mine, in the Garrison district, and the output was also shipped to Trail, British Columbia.

In the Philipsburg district, Granite County, the only mining operation reported for 1951 was that of Soluble Phosphates, Ltd., Maxville, which mined and shipped a small quantity of low-grade phosphate rock from its Maxville mine.

Digitized by Google

The Williams Phosphate Corp. was reported to have begun development of its phosphate-rock property near Alder, Madison County, in 1951 and to have begun installation of a primary crusher and ore bin.

The Victor Chemical Works operated its Maiden Rock and Canyon Creek mines near Melrose and produced phosphate rock for use in its electric smelter furnaces at Silver Bow.

Utah.—The only phosphate-rock-producing company in Utah in 1951 was the Pearl Phosphate Co. (307 South Central Ave., Ontario, Calif.), formerly the Pearl & Toland Phosphate Co., which operated its property at the south end of the Crawford Mountains in Rich County, northeastern Utah, near Woodruff. Most of the material was shipped for direct application to the soil.

Wyoming.—The reported production and shipments of Wyoming phosphate rock in 1951 showed a considerable increase over 1950. The State is an important producer of phosphate rock and stands in third place in the Western States group.

Two companies produced phosphate rock in Wyoming in 1951—the San Francisco Chemical Co., by far the larger producer, and Phosphate Mines, Inc. The San Francisco Chemical Co., operated the Leefe mine near Sage, Wyo. Phosphate Mines, Inc., Kemmerer, Wyo., mined a small quantity of phosphate rock in 1951 but shipped a much larger amount from stock for direct application to the soil.

Phosphate Fertilizer, Inc., Kemmerer, Wyo., was reported to have begun construction in 1951 of a fertilizer plant of 100 tons daily capacity at Phosphate near Kemmerer for processing phosphate rock, using a German process involving the heating of the phosphate rock in rotary kilns to render it soluble in ammonium citrate solution, then cooling and crushing the material for marketing.

CONSUMPTION AND USES

The apparent consumption of phosphate rock in the United States in 1951 increased 927,000 long tons to a record high of 9,508,000 tons from 8,581,000 tons in 1950.

TABLE 8.—Apparent consumption [1] of phosphate rock in the United States, 1946–51, in long tons

Year	Long tons	Year	Long tons
1946	6,221,525	1949	7,735,005
1947	7,425,784	1950	8,580,925
1948	7,700,081	1951	9,507,951

[1] Quantity sold or used by producers, plus imports minus exports.

Data regarding the sales of phosphate rock by uses both for individual States and for the United States are shown in table 9.

Details regarding the 1950–51 consumption of phosphatic commercial fertilizers are published annually by the United States Department of Agriculture.[6]

PRICES

Prices for phosphate rock were included under the general price freeze order of January 26, 1951 (General Ceiling Price Regulations—GCPR—January 26, 1951) in which prices were set at the highest level reached in the base period between December 19, 1950, and January 25, 1951. No changes were reported in the trade journals

[6] Scholl, Walter, and Wallace, H. M., Consumption of Commercial Fertilizers in U. S., 1950–51: Agric. Chem., vol. 7, No. 6, June 1952, pp. 33–40.

during 1951 in the price quotations for Florida land pebble or Tennessee brown-rock phosphate. The price quotations of the Oil, Paint, and Drug Reporter as of January 8, 1951, and December 31, 1951, are given in table 11. Quotations for Western States phosphate rock are not given in the trade journals.

TABLE 11.—Prices per long ton of Florida and Tennessee unground, washed, and dried phosphate rock, in bulk, f. o. b. cars at mine, in 1951, by grades

[Oil, Paint and Drug Reporter]

Grades (percent) [1]	Florida land pebble		Tennessee brown rock	
	Jan. 8, 1951	Dec. 31, 1951	Jan. 8, 1951	Dec. 31, 1951
70/68 B. P. L.	$4.35–4.40	$4.35–4.40		
72/70 B. P. L.	5.00	5.00		
75/74 B. P. L.	6.00	6.00		
77/76 B. P. L.	7.00	7.00		
27–26 P_2O_5			$6.45	$6.45
30–29 P_2O_5			7.21	7.21

[1] B. P. L. signifies bone phosphate of lime, $Ca_3(PO_4)_2$.

FOREIGN TRADE [7]

Data on imports and exports of phosphate rock and other phosphatic materials are shown in tables 12 to 15. The imports of phosphate rock in 1951 were principally from the Netherlands Antilles (97 percent). The balance came from Belgium, Mexico, and Canada, in the order named.

Sales or shipments of phosphate rock for export as reported by domestic producers to the Bureau of Mines are given in the section on Consumption and Uses.

TABLE 12.—Phosphate rock and phosphatic fertilizers imported for consumption in the United States, 1950–51

[U. S. Department of Commerce]

Fertilizer	1950		1951	
	Long tons	Value	Long tons	Value
Phosphates, crude, not elsewhere specified	87,173	$1,113,974	89,823	$1,379,767

[5] Revised figure.

BASIC SLAG

Basic slag is a comparatively limited source of agricultural phosphorus in the United States. Domestic production comes from a single company smelting a phosphatic iron ore in the Birmingham, Ala., district. No figures on production or sales are released for publication by this company. Annual imports are negligible. In 1950, 179 long tons were imported; in 1951, only 96 tons. No exports were reported.

Platinum-Group Metals

By James E. Bell and Kathleen M. McBreen

GENERAL SUMMARY

FEATURES of the platinum-group metals in 1951 were large total domestic consumption for the second consecutive year and adoption of controls on platinum sales. Prices continued high. Sales of platinum were substantially smaller than in 1950, but sales of palladium rose sharply and exceeded those of platinum over an annual period for the first time on record. Inadequate supplies of platinum led to the issuance in April of National Production Authority Order M–54 prohibiting the sale of platinum for unessential uses. Total imports of the platinum-group metals were at a new high for the second consecutive year. The strong demand for the platinum-group metals was due largely to requirements for the military program and defense-supporting industries.

[1] Includes Alaska.
[2] Revised figure.

Refinery production of platinum (new and secondary combined) in the United States in 1951 was 35 percent below that of 1950, and imports of refined platinum were 31 percent greater. Domestic consumption, as measured by sales, declined 32 percent, and stocks of

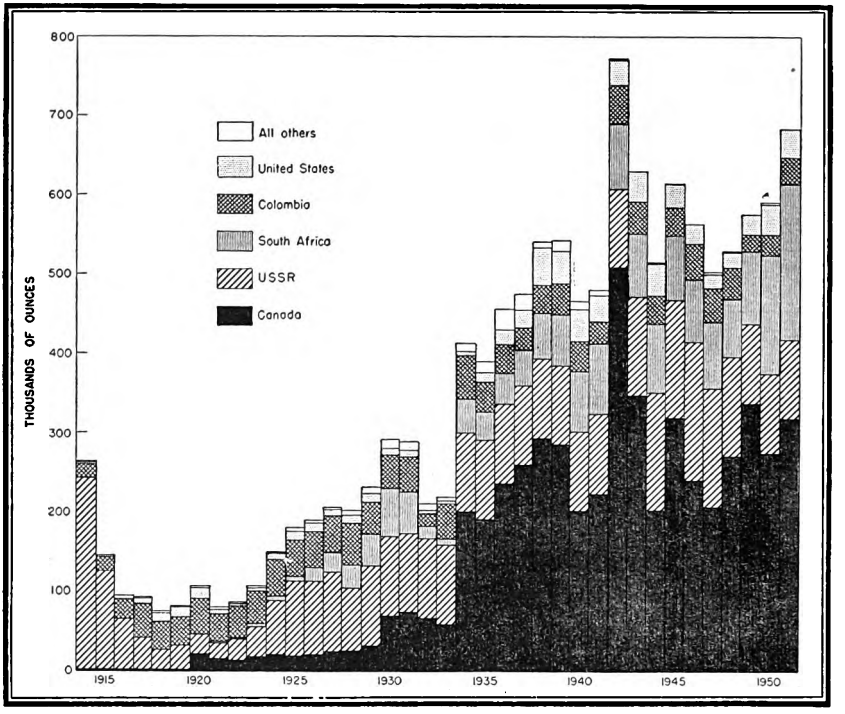

FIGURE 1.—World production of platinum-group metals, 1914–51.

refiners and dealers rose 11 percent. The chemical industry was the largest user, increasing to 47 percent of the total sales in 1951 from 37 percent in the preceding year.

Refinery production of palladium in the United States in 1951 was 5 percent above that of 1950, and imports of refined palladium were 62 percent greater. Stocks of refiners and dealers increased 28 percent. Domestic consumption, as measured by sales, rose 48 percent. The electrical industry maintained its accustomed position as the largest user, taking 52 percent of the total sales.

Refinery production of iridium, of osmium, of rhodium, and of ruthenium in the United States in 1951 was higher than in 1950, particularly that of rhodium. Imports of iridium, osmium, and ruthenium were each smaller in 1951 than in 1950, but those of rhodium were greater. Domestic consumption of the four metals together decreased 17 percent, while stocks of refiners and dealers rose 10 percent.

Total imports of platinum-group metals into the United States in 1951 were 41 percent greater than in the previous record year 1950.

In July the Rustenburg Platinum Mines, Ltd., the principal producer of platinum-group metals in South Africa, announced plans to increase its output substantially. Figure 1 shows graphically the trend in world production of platinum-group metals since 1914.

Digitized by Google

Government Regulations.—In the face of serious shortages of platinum for the military program and essential civilian requirements, and as a result of meetings on February 19, 1951, and March 16, 1951, between members of the Industry Advisory Committee for Platinum and officials of various Government agencies, National Production Authority Order M–54 was issued effective April 1, 1951. This order forbade purchase of platinum for investment or speculative purposes and prohibited its delivery or acceptance for use in many consumer items, largely jewelry. Platinum in the inventory of manufacturers of the prohibited items on April 1 was exempted from the provisions of the order.

CRUDE-PLATINUM PRODUCTION

Mine returns and refinery reports indicate a domestic mine output of 36,951 troy ounces of platinum-group metals in 1951 compared with 37,855 ounces in 1950. This production includes crude platinum recovered from placer-platinum deposits in the Goodnews Bay district in southwestern Alaska, byproduct crude platinum recovered from gold placer-mining operations in California, and platinum-group metals contained in small quantities in some gold and copper ores and recovered as a byproduct of smelting and refining. No production of byproduct crude platinum was reported in Montana or Oregon in 1951.

Purchases.—United States buyers reported the purchase in 1951 of 39,426 ounces of crude platinum from Alaska, California, Colombia, Union of South Africa, British Columbia (Canada), and Panama. The corresponding quantity in 1950 was 69,056 ounces.

RECOVERY OF REFINED PLATINUM-GROUP METALS

New Metals Recovered.—Reports from refiners indicate recovery in the United States of 53,061 ounces of new platinum-group metals in 1951, a 27 percent decrease from that in 1950. Seventy-nine percent of this output was recovered from crude platinum, chiefly from Alaska and Colombia, and 21 percent as a byproduct of gold and copper ores, the same proportions as in 1950.

Secondary Metals Recovered.—The domestic recovery of platinum-group metals in 1951 from the refining of scrap, sweeps, etc., was 53,358 ounces compared with 58,113 ounces in the preceding year.

Substantial quantities of wornout catalysts, spinnerets, laboratory ware and equipment, and other products are returned to refiners for refining or reworking. The refined platinum-group metals recovered from this source (or their equivalent in refined metals) are returned to the consumers. The platinum-group metals so recovered are not considered secondary production and are not included in the figures for secondary metals.

Technology.—An article on spectrographic methods of analysis for minor constituents in palladium and platinum refinery sponge was published in 1951.[1]

CONSUMPTION AND USES

Sales of the platinum-group metals to consumers in the United States totaled 462,535 troy ounces in 1951 compared with 495,945 ounces in the preceding year, a 7-percent drop.

Sales of platinum to domestic consumers were 209,695 ounces in 1951 and represented 45 percent of the total sales of platinum-group metals; corresponding figures for 1950 were 308,998 ounces and 62 percent. The chemical industry was the largest user in 1951 and accounted for 47 percent of the domestic platinum sales, followed by the electrical industry with 33 percent. Reflecting the restrictions imposed by Order M–54, sales for jewelry and decorative uses declined from 41 percent of the total platinum sales in 1950 to 12 percent in 1951. Sales of platinum for dental and medical, and miscellaneous uses were, respectively, 20 and 34 percent lower in 1951 than in 1950.

TABLE 4.—Platinum-group metals sold to consuming industries in the United States in 1950 and 1951, in troy ounces

Industry	Platinum	Palladium	Iridium, osmium, rhodium, and ruthenium	Total
1950				
Chemical	114,430	16,673	13,875	144,978
Electrical	45,229	80,024	3,316	128,569
Dental and medical	18,182	18,359	371	36,912
Jewelry and decorative	127,374	35,293	12,810	175,477
Miscellaneous and undistributed	3,783	107	6,119	10,009
Total	308,998	150,456	36,491	495,945
1951				
Chemical	97,813	38,527	16,834	153,174
Electrical	70,144	116,601	3,340	190,085
Dental and medical	14,476	30,497	162	45,134
Jewelry and decorative	24,759	35,500	5,379	65,638
Miscellaneous and undistributed	2,504	1,420	4,580	8,504
Total	209,695	222,545	30,295	462,535

In 1951, 222,545 ounces of palladium were sold to domestic consumers, a gain of 72,089 ounces over the preceding year and the largest on record, accounting for 48 percent of the total sales of the group. There were increased sales for all uses, particularly the electrical industry. The distribution of consumption by uses was: Chemical 17 percent, electrical 52, dental and medical 14, jewelry and decorative 16, and miscellaneous less than 1.

Iridium, osmium, rhodium, and ruthenium together accounted for 7 percent of the total of platinum-group metals sold in 1951, the same as in 1950. By quantity the sales were as follows: Iridium 5,556 ounces, osmium 2,441 ounces, rhodium 15,634 ounces, and ruthenium 6,664 ounces—a total of 30,295 ounces.

The platinum-group metals are used as pure metals, combined, clad, or alloyed with other metals. (*See* page 801 of the Platinum and Allied Metals chapter of Minerals Yearbook, 1943, for a comprehensive table showing uses of these metals.)

The chemical applications of the platinum-group metals arise from their catalytic activity and their resistance to corrosion and other chemical action, even at high temperatures. Catalytic uses include the production of nitric and sulfuric acids, hydrogenation and dehydrogenation, the synthesis of hydrocarbons, and hydroxylation. A recent and expanding development is the use of platinum as a catalyst for producing high-octane gasoline from low-grade and natural gasoline. Pure platinum and iridium-platinum alloys are used as insoluble anodes in various electroplating processes, and chemical laboratories have long used platinum for crucibles, electrodes, and other ware and equipment. Platinum-gold and rhodium-platinum alloys have been used many years in spinnerets for making rayon fiber from viscose. Fiber glass in rapidly increasing quantities is produced in a somewhat similar way by forcing molten glass through banks of platinum nozzles, whence it emerges in fine streams that are stretched to filaments of minute diameter.

The platinum-group metals have numerous electrical applications

Digitized by Google

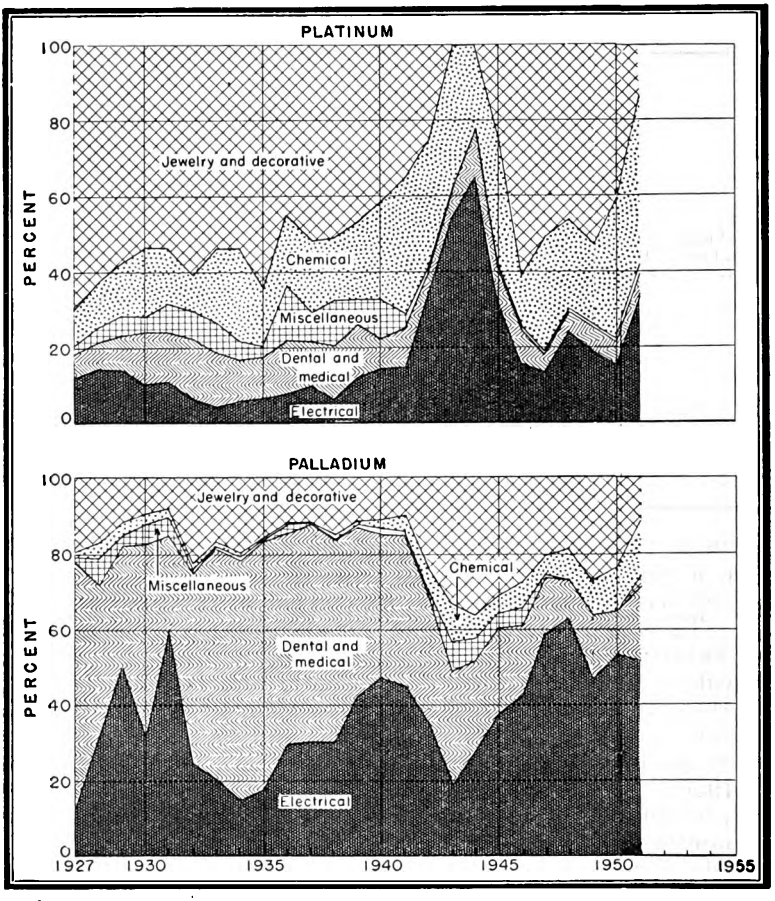

FIGURE 2.—Sales of platinum and palladium to various consuming industries in the United States, 1927–51, as percent of total.

based on their resistance to tarnishing by oxidation or sulfidation, resistance to spark erosion, high melting temperatures, and good mechanical properties. Palladium is used extensively in the contacts of telephone relays. Platinum, either pure or hardened with iridium or ruthenium, is used for contacts in voltage regulators, thermostats, relays, and contacts in high-tension magnetos. Sparkplugs equipped with platinum-alloy electrodes have long life and resistance to fouling. Platinum and platinum alloys are employed in numerous delicate electrical and laboratory instruments and in electronic tubes. Rhodium electroplate provides a surface of high reflectivity for reflectors.

Because of their strength, workability, and resistance to tarnish, alloys of platinum and palladium are used extensively for dentistry in cast and wrought forms and as pins and anchors.

Platinum hardened with iridium or ruthenium is widely accepted as the ideal metal in the jewelry and decorative arts, particularly for gem-set jewelry. Palladium alloyed with ruthenium is gaining acceptance for jewelry, particularly in Europe. Both platinum and palladium are beaten into leaf for use in signs, book bindings, etc.

STOCKS

Stocks of platinum-group metals in all forms in the hands of refiners, dealers, and importers, as reported to the Bureau of Mines, totaled 313,891 troy ounces on December 31, 1951, compared with 266,562 ounces a year earlier, an increase of 18 percent.

TABLE 5.—Stocks of platinum-group metals held by refiners, importers, and dealers in the United States, December 31, 1947–51, in troy ounces

Year	Platinum	Palladium	Iridium, osmium, rhodium, and ruthenium	Total
1947	133,300	167,364	36,859	**337,523**
1948	146,823	142,211	34,540	**323,574**
1949	138,049	122,408	35,587	**296,044**
1950	125,234	107,854	33,474	**266,562**
1951	138,977	138,099	36,815	**313,891**

PRICES

The quoted retail prices of the platinum-group metals remained unchanged during 1951 and were as follows per fine troy ounce: Platinum $93, palladium $24, iridium $200, osmium $200–$215, rhodium $125, and ruthenium $93. However, substantial sales of platinum are reported to have been made at prices higher than $93. During 1951 the two London refineries that handle the production of platinum-group metals of Canada and South Africa maintained their respective prices for platinum at £33¼ ($93.10) and £27 ($75.60) per ounce, while reserving most of the supplies available to them for essential requirements; prices for the remainder were bid up considerably in the free market. The London price for palladium ranged from £8 ($22.40) to £9 ($25.20) per ounce during 1951.

United States buyers reported purchases at $73.18 to $103.51 per ounce for domestic and foreign crude platinum in 1951. This price range resulted chiefly from fluctuations in quotations for refined metals and variations in the iridium content of the crude platinum.

FOREIGN TRADE [2]

Imports.—Imports of platinum-group metals into the United States in 1951 totaled 41 percent more than those in the previous record year 1950 and thus reached an alltime high for the second consecutive year. The principal sources were Canada (288,022 ounces), Colombia (25,181 ounces), Japan (114,731 ounces), Netherlands (43,098 ounces) United Kingdom (20,442 ounces), Union of South Africa (77,796 ounces), and U. S. S. R. (16,075 ounces). Imports of refined metals in 1951 totaled 537,812 troy ounces compared with 378,996 ounces (revised) in 1950; imports of unrefined metals totaled 63,594 ounces compared with 48,551 ounces (revised). Imports of refined platinum, palladium, and rhodium were 31, 62, and 57 percent greater, respectively, in 1951 than in 1950; and imports of refined iridium, osmium, and ruthenium were 54, 13, and 9 percent less, respectively.

[1] On the basis of detailed information received by the Bureau of Mines from importers, certain items recorded by the U. S. Department of Commerce as "grain and nuggets," and "sponge and scrap" have been reclassified and included with other groups in this table.
[2] U. S. Department of Commerce categories are in terms of metal content. It is believed, however, that in many instances, gross weights are actually reported.
[3] Revised figure.

Exports.—Exports of refined platinum (including scrap) decreased to 8,760 ounces in 1951 from 12,753 ounces in 1950; exports of the other platinum-group metals (including scrap) rose to 52,088 ounces from 24,946 ounces. France was the largest buyer of platinum in 1951 taking 4,529 ounces, followed by Germany with 1,744 ounces. For the other platinum-group metals, Germany was the largest market, taking 35,866 ounces.

WORLD REVIEW

Canada.—Most of the output of platinum-group metals of Canada is obtained as a byproduct from the nickel-copper ores of the Sudbury district; a small quantity is recovered incident to gold-placer mining in British Columbia. According to the Dominion Bureau of Statistics, the total production of Canada in 1951 was 154,956 troy ounces of platinum and 162,480 ounces of other platinum-group metals; corresponding figures for 1950 were 124,571 ounces and 148,741 ounces.

Deliveries of platinum-group metals by The International Nickel Co. of Canada, Ltd., were 375,438 ounces in 1951 compared with 267,316 ounces in 1950.

Digitized by Google

Colombia.—The production of platinum-group metals of Colombia results from placer-mining operations in the Choco district, mostly by dredges. The crude material averages about 85 percent platinum-group metals. Figures for the output are difficult to obtain. The South American Gold & Platinum Co., which supplies most of the production, recovered 20,344 ounces of crude platinum-group metals in 1951 compared with 25,968 ounces in 1950.

[5] Year ended June 30 of year stated.
[6] Less than 0.5 ounce.

Union of South Africa.—Platinum-group metals are obtained in the Union of South Africa from two sources—as an osmiridium byproduct from gold mining on the Rand and as the principal product of mining operations on the Merensky Reef, a horizon of the Bushveld igneous complex in the Transvaal. Detailed discussion of these two sources was included in the Minerals Yearbook, 1950, chapter on Platinum-Group Metals (pages 1032–1033).

The Rustenburg Platinum Mines, Ltd., has absorbed a number of former producers and in 1951, as in 1950, was the only concern mining on the Merensky Reef. This company announced plans in 1951 to expand its plant capacity from 75,000 tons of ore per month to 125,000 tons, reaching full production in 1953. At this scale, the indicated output of platinum-group metals is around 400,000 ounces annually.

During the last 15 years the average recovery of osmiridium on the Rand was somewhat over 0.10 ounce per 1,000 tons of gold ore milled.

Potash

By E. Robert Ruhlman and Gertrude E. Tucker

GENERAL SUMMARY

INCREASES in both domestic production and imports of potash materials made 1951 the record year, with a total supply of over 1.6 million tons of potash (K_2O) available for consumption. Sales of domestic marketable potassium salts rose 10 percent. Exports increased both in quantity and value. Apparent consumption and producers' stocks also increased.

TABLE 1.—Salient statistics of the potash industry in the United States, 1949–51

	1949	1950 [1]	1951

Approximate equivalent K_2O..do..	1,070,311	1,411,646	1,653,188

[1] Revised figures except short tons and approximate K_2O equivalent of exports.
[2] Estimate by Bureau of Mines.
[3] Quantity sold by producers, plus imports, minus exports.

An article relating to the determination of potash [1] and an abstract of a paper presented at the Institute of Physics on microdetermination of Na and K were published in 1951.[2]

PRODUCTION AND SALES

The upward trend in the production of domestic marketable potassium salts continued in 1951. Both production and sales increased about 10 percent in quantity over 1950, and the value of the potassium salts sold in 1951 was 13 percent greater than in 1950. Production of potassium salts in 1951 totaled 2,474,870 short tons, with an equivalent K_2O content of 1,420,323 tons. Sales were 2,451,913 tons, with an equivalent K_2O content of 1,408,408 tons. Producers' stocks increased 22,957 tons during the year to a total of 62,597 tons on December 31, 1951. The total value of sales was $44.8 million in 1951. The average value per ton of potassium salts sold in 1951 was $18.27, compared with $17.90 (revised) in 1950.

The production of both grades of muriate of potash (60–62 percent K_2O minimum and 48–50 percent K_2O minimum) increased in 1951 over 1950. Production of the higher-grade muriate rose 11 percent to a new high of 2,047,793 short tons, and the production of the lower-grade muriate rose 3 percent to 155,797 short tons. The production of manure salts dropped to 19,775 tons. The combined production of sulfate of potash and sulfate of potash-magnesia increased 13 percent in 1951 (as compared to 1950) to 251,505 tons.

California, New Mexico, and Utah supplied nearly all of the reported production of domestic marketable potassium salts, over 86 percent coming from the Permian deposits of southeastern New Mexico. A fourth company in the Carlsbad area, the Duval Sulphur & Potash Co., began production late in 1951.

The potash-producing companies in the United States in 1951, by States, were as follows:

California:
- The American Potash & Chemical Corp., 3030 W. 6th St., Los Angeles 54, Calif. (plant at Trona, on Searles Lake, Calif.).
- A. M. Blumer, 465 California St., San Francisco, Calif. (byproduct from Santa Cruz Cement Co., Davenport, Calif.).

Maryland:
- North American Cement Corporation, 41 East 42nd St., New York 17, N. Y. (plant at Security, Md.).

Michigan:
- The Dow Chemical Co., Midland, Mich. (brine wells and plant near Midland, Mich.).

New Mexico:
- Duval Sulphur & Potash Co., Mellie Esperson Bldg., Houston 2, Tex. (mine and plant near Carlsbad, N. Mex.).
- International Minerals & Chemical Corp., 20 N. Wacker Dr., Chicago, Ill. (mine and plant near Carlsbad, N. Mex.).
- Potash Company of America, Inc., Carlsbad, N. Mex. (mine and plant near Carlsbad, N. Mex.).
- United States Potash Co., Inc., 30 Rockefeller Plaza, New York 20, N. Y. (mine and plant near Carlsbad, N. Mex.).

Utah:
- Bonneville, Ltd., 540 West Seventh South, Salt Lake City 4, Utah (plant near Wendover, Utah).

REVIEW BY STATES

California.—The American Potash & Chemical Corp. continued to be the leading potash-producing company in California. Potassium chloride and potassium sulfate were marketed from a potash-bearing brine pumped from the crystalline salt mass of Searles Lake. In 1951 the Mathieson Chemical Corp. acquired the 25-percent interest in the American Potash & Chemical Corp. formerly held by the Heyden Chemical Corp.

A second producer of potassium compounds in California is A. M. Blumer of San Francisco. For many years his organization has been distributing potash-bearing agricultural lime. This material is portland cement flue dust and at present most of it is obtained from the Cottrell precipitators at the Davenport plant of the Santa Cruz Portland Cement Co. The material is largely lime in the form of calcium carbonate and calcium oxide. It contains variable amounts of potassium sulfate up to as much as 15 percent equivalent K_2O. No attempt is made to sort the material or to control the potash content.[3]

Maryland.—The North American Cement Corp., the only potash producer in Maryland, produced, as a byproduct, an impure low-

[3] California Journal of Mines and Geology, The Mineral Industry of California—Its Status and Relation to National Defense in 1950-51: Vol. 48, No. 1, January 1952, p. 117.

Digitized by Google

grade sulfate of potash at its cement plant at Security, Washington County, near Hagerstown. The product was sold for agricultural use.

Michigan.—The Dow Chemical Co. continued to produce potassium chloride from its brine wells at Midland. This was the only reported potash producer in Michigan in 1951.

New Mexico.—Mine production of crude potassium salts in the Carlsbad region of New Mexico reached a new high of over 6.6 million short tons, a 14-percent increase above 1950. The grade (K_2O equivalent) of the crude salts mined decreased in 1951 to 20.40 percent compared to 20.65 percent in 1950 and 21.00 percent in 1949. Production and sales of marketable salts both showed increases in 1951.

The four producing companies—Duval Sulphur & Potash Co., International Minerals & Chemical Corp., Potash Company of America, and the United States Potash Co.—mined sylvite ore (sylvinite), and International Minerals & Chemical Corp. also mined langbeinite. Most of the sylvite ore (potassium chloride) was processed to yield 60-percent or higher-grade muriate. The langbeinite was treated by the producer to yield potassium sulfate and potassium-magnesium sulfate.

An article published in 1951 described the stratigraphic and mineralogic relationships of the potash beds in New Mexico.[4]

TABLE 4.—Production and sales of potassium salts in New Mexico, 1947–51, in short tons

Year	Crude salts [1]		Marketable potassium salts				
	Mine production		Production		Sales		
	Gross weight	K_2O equivalent	Gross weight	K_2O equivalent	Gross weight	K_2O equivalent	Value
1947	4,655,732	965,583	1,625,870	866,070	1,659,266	880,605	$28,035,675
1948	5,108,372	1,069,675	1,841,054	964,940	1,850,976	967,945	29,177,328
1949	4,852,903	1,018,886	1,733,739	927,621	1,744,427	932,497	27,950,111

[1] Sylvite and langbeinite.

The Duval Sulphur & Potash Co. mine and plant were nearly completed in 1951, and preliminary production was begun. Full production was planned for early 1952.

Freeport Sulphur Co. continued exploration for potash in Eddy and Lea Counties approximately 32 miles east of Carlsbad. Additional diamond drilling was planned before any definite production program would be announced.

International Minerals & Chemical Corp. continued development of an extension of the present ore body. Sinking of the third shaft was completed, and a fourth shaft was begun. Both new shafts will be for ventilation and service. All ore will continue to be hoisted through No. 1 shaft. This new ore body is considerably larger than the original. In 1951, the corporation published a booklet describing its operations.[5]

The new plant of the Potash Company of America at Dumas, Tex., was put into operation early in 1951, using potassium chloride from the company mines in the Carlsbad region to produce potassium sulfate and hydrochloric acid. At the Carlsbad plant improvements included expansion of the flotation section of the mill, increases in capacity of the steam and electric plants, expansion of the chemical-grade KCl plant, and installation of two Joy continuous miners. The new shaft in which a freezing method was being used to consolidate the quicksands and to prevent water inflow during sinking, reached a depth of 700 feet at the end of 1951. Total depth was to be 800 feet. A description of the sinking method was published.[6]

The Southwest Potash Corp., a wholly-owned subsidiary of the American Metal Co., Ltd., continued construction of its surface plant and development of the mine. At the end of 1951, the overall project was about 65 percent completed. Production was scheduled to begin in August 1952.[7]

In 1951, the United States Potash Co. began a 3-year program of construction and expansion. The major projects included construction of a new office building in Carlsbad, installation of additional equipment in the refinery, and sinking of a new shaft nearly 6 miles northeast of the No. 1 shaft. This new shaft, for ventilation and the transportation of men and supplies, was to be 15 feet in diameter and 1,300 feet deep. New equipment put into service during the year included several Diesel-powered items, radio telephones for better communication, additional ventilation fans, a new hoist at the No. 2 shaft, and other equipment to improve the operations and to protect the health and safety of the men.

Utah.—Bonneville, Ltd., the only reported producer of potash in Utah in 1951, continued to produce potassium chloride at its plant near Wendover, Tooele County, from the brines of Salduro Marsh. The company reported completion of 8 more wells to recover brine from about 1,200 feet below the surface. Other improvements included additional electrical capacity and equipment and 3 more Diesel caterpillar 20-ton wagons used to haul the potash salts to the mill.

The Kalunite plant in Salt Lake City was acquired by Vitro Chemical Co., from J. R. Simplot for use as a uranium and vanadium refinery.[8]

CONSUMPTION

The apparent consumption (producers' sales plus imports minus exports) of potash (K_2O) rose over 17 percent in 1951 to 1,653,188 short tons of K_2O as compared with 1950. The apparent consumption and sales of domestic producers as reported to the Bureau of Mines are shown in figure 2. The sales of domestic potash (K_2O) were 85 percent of apparent consumption in 1951 compared with 90 percent in 1950.

According to the American Potash Institute (press notice, March 17, 1952):

Deliveries of potash in North America again made a new record in 1951, amounting to 3,004,666 tons of salts containing an equivalent of 1,707,525 tons K_2O. This was an increase of 241,926 tons K_2O or 17 percent over 1950. Deliveries by the five leading domestic producers were the highest ever achieved, 1,382,408 tons K_2O. Imports were 325,117 tons K_2O, also a record high.

Deliveries for agricultural purposes in the continental United States for 1951 were 1,490,178 tons K_2O, an increase of 226,059 tons over 1950. Canada received 60,792 tons K_2O, Cuba 14,876 tons, Puerto Rico 27,766 tons, and Hawaii 14,214 tons. Exports to other countries amounted to 12,270 tons K_2O.

In this country the potash was delivered in 45 States and the District of Columbia. Illinois and Ohio with over 120,000 tons K_2O were the leading States in deliveries of agricultural potash and were followed in order by Georgia, Virginia, North Carolina, Florida, and Indiana, each taking more than 90,000 tons K_2O during the year. Due to shipments across State lines, consumption does not necessarily correspond to deliveries within a State.

The 60 percent muriate of potash continues to be by far the most popular material, comprising 76 percent of the total K_2O delivered for agricultural purposes. The 50 percent muriate of potash made up 15 percent, manure salts less than 1 percent, and sulfate of potash and sulfate of potash-magnesia 8 percent of deliveries.

Deliveries for chemical purposes in 1951 were 131,359 tons of muriate of potash containing an equivalent of 82,512 tons K_2O and 9,761 tons of sulfate of potash containing 4,916 tons K_2O. The total chemical deliveries of 87,429 tons K_2O were 7,082 tons or 9 percent more than in 1950.

Deliveries of agricultural and chemical potash in North America from 1941 to 1951 are shown in figure 3.

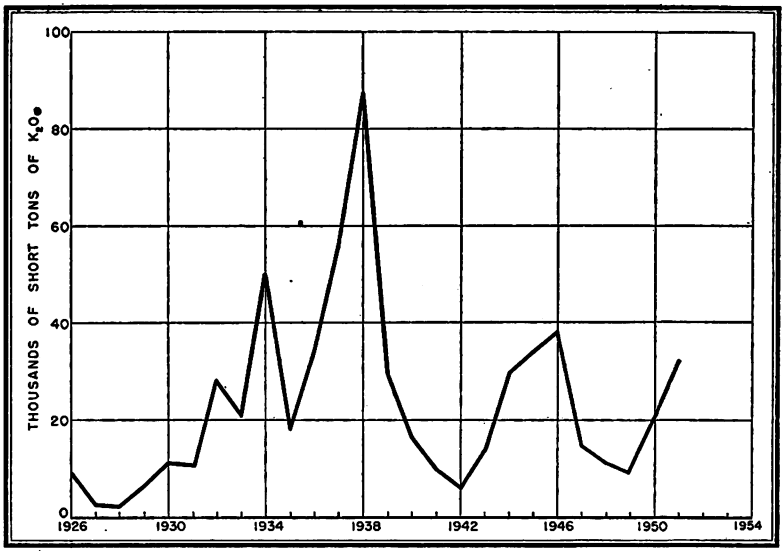

FIGURE 4.—Producers' stocks of potassium salts at end of year, 1926–51, in short tons of equivalent potash (K_2O).

PRICES

Prices for agricultural grade potash were frozen by GCPR (General Ceiling Price Regulation—issued by the Office of Price Stabilization) at the highest price charged during the base period of December 19, 1950–January 25, 1951. Potash prices in the early months of 1951 were the same as those listed in the producers' price schedules for the 1950–51 season. Supplementary Regulation 59 to GCPR, effective September 15, established ceiling prices for muriate of potash as follows:

Shipping point:	*Ceiling per unit (20 lb.)*
Carlsbad, N. Mex	$0.42
Wendover, Utah	.42
Trona, Calif	.505

The American Potash & Chemical Corp. issued its price schedule on May 15, 1951, for agricultural-grade Trona potash for the 1951–52 season. Its list price for muriate of potash 60 percent K_2O minimum, f. o. b. Trona, Calif., bulk in carlots of not less than 40 tons, was 50.5 cents per unit K_2O and for sulfate of potash 95–98 percent K_2SO_4 was 86 cents per unit K_2O. The list prices of both muriate and sulfate were subject to seasonal discounts. There were additional charges for shipments in bags.

The New Mexico producers' price schedules of agricultural-grade potash for the 1951–52 season, issued during April, May and June, 1951, are shown in table 7.

Do.	Run-of-mine 20 percent K_2O minimum.	Sunshine State	U. S. P.	June 1–May 31	.21
Sulfate of potash	48.6 percent K_2O minimum.	International	I. M. & C.	June 1–May 31	.745
Sulfate of potash-magnesia.	Basis 40 percent K_2SO_4, 18% MgO.	International Sulpho-mag.	do.	June 1–May 31	[3] 16.00

[1] Bulk in carlots (minimum 40 tons). Subject to seasonal discounts.
[2] International Minerals & Chemical Corp. quoted muriate of potash, 50–51 percent K_2O, packed in 5-ply plain paper bags, 100 pounds each, at $25.75 per short ton June 1–May 31.
[3] Per short ton.

FOREIGN TRADE [9]

Imports.—Total imports of potash salts increased over 50 percent in 1951 over 1950, the highest reported since 1938, rising from 381,490 short tons (200,529 tons K_2O) in 1950 to 574,361 tons (313,454 tons K_2O) in 1951. This was due entirely to a large increase in the arrivals of potassium-bearing fertilizer materials. The total value of imports rose over 4½ million dollars to $18,543,112 in 1951. Germany, Spain, and France supplied 65, 17, and 10 percent, respectively, of the potash imports in 1951.

Potash for fertilizer use constituted 98 percent of the total K_2O imports in 1951 and for chemical use 2 percent.

The average K_2O content of potash imports increased from 52½ to 54½ percent in 1951 as compared to 1950. Muriate (chloride), the principal potassium salt imported in 1951, came mainly from Germany, Spain, and France, with minor amounts from Belgium-Luxembourg and Poland-Danzig. Germany supplied substantial amounts of potassium sulfate and carbonate, 45,917 and 1,605 short tons, respectively. Imports of crude sodium-potassium nitrate from Chile were 73 percent less than in 1950.

[9] Figures on imports and exports compiled by M. B. Price and E. D. Page of the Bureau of Mines, from records of the U. S. Department of Commerce.

Exports.—Potash materials exported from the United States in 1951 rose 6 percent in quantity and 37 percent in value over 1950, with both fertilizer and chemical grades showing increases. Canada, Brazil, and Cuba received 94 percent of the 109,139 short tons of the fertilizer potash exported in 1951, with smaller amounts going mainly to countries in the Western Hemisphere. The exports of chemical potash materials (15,112 tons) containing 7,556 tons of K_2O were widely distributed, Canada, Brazil, Sweden, and Mexico being the leading recipients.

WORLD REVIEW

Available statistics of potash output in the various producing countries, as well as estimated totals of world production, are shown in table 12.

Canada.—Western Potash Corp., Ltd., has the potash mineral rights to 120,000 acres—100,000 acres of crown land and 20,000 of Canadian Pacific Railroad lands—in the Unity district, Saskatchewan. The company has done considerable research work on brining methods of extracting the potash, which is over 4,000 feet below the surface. Continued drilling has shown that the potash beds are about 11 feet thick and extend over 12 miles. The lateral extent of the beds was not known by the close of 1951.

France.—Modernization of the potash mines and plants under the Monnet plan, as announced in 1946, was progressing ahead of schedule. Modernization and replacement of mining equipment had increased the mine output per man per day to approximately 6 metric tons. Refinery modernization and expansion were not completed by the end of 1951.

The marketing of all French potash was controlled by the Société Commerciale des Potasses d'Alsace. In general, potash was sold abroad for "what the market will bear."[10]

Germany (Western).—Expansion of potash production through rehabilitation of existing facilities and development of new deposits again made West Germany one of the leading producers in 1951, with a reported output exceeding 1 million metric tons of K_2O. Operations at the Königshall-Hindenburg mine and the mine at Bokeloh were resumed. At the former, high-grade salts containing 25 percent to 27 percent K_2O were found.[11]

A new shaft was being sunk at Buggingen, Baden, on the east bank of the Rhine, searching for a possible extension of the French deposits in Alsace.

Limited coal supplies seriously hampered further expansion.

Israel and Jordan.—The plant of the Palestine Potash, Ltd., at the south end of the Dead Sea, remained idle pending completion of the road from the plant to Beersheba. Production was scheduled to resume late in 1952. The problems of obtaining enough fresh water and securing foreign capital were serious handicaps to the company.[12]

Spain.—Plans for the construction of a plant to produce polyvinyl chloride and caustic potash in Mondoz were announced by Etino-Quimica S. A. The chloride was to be used by the company in manufacturing plastics and the potash exported as potassium hydroxide.[13]

According to the National Industrial Plan, as announced by the Ministry of Industry and Commerce in January 1950, the Potasas de Navarra, Pamplona, Province of Navarra, was scheduled to begin exploration for new potash deposits during the second half of 1951.[14]

United Kingdom.—British Potash Development Co., Ltd., was formed in 1951 to "develop, extend and carry on the winning of potassium, sodium and magnesium salts and other minerals, metals, lodes, ores and other raw materials, etc.," especially the potash deposits discovered by the work of Imperial Chemical Industries, Ltd., Fisons, Ltd., and the Anglo-Iranian Oil Group, in the North Riding district of Yorkshire.[15]

In the past the United Kingdom has depended upon foreign sources for all its requirements of potash. The Yorkshire deposits, when developed, would save the country about 7 million pounds sterling a year.

These deposits were described in the Potash chapter of Minerals Yearbook, 1950 (p. 1051).

Salines—Miscellaneous

By Joseph C. Arundale and F. M. Barsigian [1]

GENERAL SUMMARY

THE HIGH LEVEL of industrial activity during 1951 was reflected in record sales of many of the miscellaneous salines—calcium chloride, bromine, soda ash, salt cake, and borax. Some shortages in these basic raw materials were reported early in 1951, but by the end of the year expanded production facilities and a leveling in demand put supply and demand almost in balance.

CALCIUM CHLORIDE

Sales of calcium chloride recovered from natural brines in 1951 exceeded those in any previous year. Stabilization of dirt-road surfaces and dust control continued as the most important use. The role of calcium chloride in the construction and maintenance of roads was discussed in several articles.[2] In these articles it was concluded that the extent and cost of maintenance of gravel-surfaced roads can be reduced, with the added advantage of dust palliation. Several examples of procedures for applying calcium chloride were also outlined.

TABLE 1.—Calcium chloride and calcium-magnesium chloride from natural brines sold by producers in the United States, 1946–51

[In terms of 75 percent (Ca, Mg) Cl_2]

Year	Short tons	Value	Year	Short tons	Value
1946	262,147	$2,278,954	1949	255,797	$3,260,675
1947	271,206	2,650,205	1950	299,821	3,801,508
1948	309,660	3,906,858	1951	328,042	4,756,242

Certain precautions are necessary in producing ready-mixed concrete during cold weather to assure adequate strength. Heating the ingredients and adding an accelerator is a method which has been used. Calcium chloride as the accelerator or as an ingredient of accelerators is sometimes used. Suggested procedures, where the use of such material is indicated, have been published.[3]

TABLE 2.—Calcium chloride imported for consumption in and exported from the United States, 1947–51

[U. S. Department of Commerce

Year	Imports		Exports	
	Short tons	Value	Short tons	Value
1947	250	$5,514	11,955	$502,818
1948	5	249	11,456	437,763
1949	(1)	20	21,094	507,845
1950	1,881	54,170	15,624	[2] 403,230
1951	813	37,451	18,637	559,284

[1] Less than 0.5 ton.
[2] Revised figure.

Another important use for calcium chloride is in "freeze-proofing" coal, iron ore, and other materials shipped in bulk in railroad cars or stockpiled in the open. It is often sprayed in solution on the ore but in some instances is applied in flake form. Equipment and procedures were described.[4]

The following companies produced calcium chloride (and calcium magnesium chloride) from natural brines in 1951: California Rock Salt Co., 2436 Hunter St., Los Angeles 21, Calif., plant at Amboy, Calif.; Hill Bros. Chemical Co., 2159 Bay St., Los Angeles 21, Calif., plant at Amboy Calif.; Michigan Chemical Corp., 500 N. Bankson St., St. Louis, Mich.; Dow Chemical Co., Midland, Mich.; Pomeroy Salt Corp., Pomeroy, Ohio, plant at Minersville, Ohio; Westvaco Chemical Division, Food Machinery & Chemical Corp., South Charleston 3, W. Va.; Wilkinson Chemical Co., Mayville, Mich.; and National Chloride Co. of America, 354 S. Spring St., Los Angeles 13, Calif., plant at Amboy, Calif.

According to Oil, Paint and Drug Reporter, the prices for calcium chloride were unchanged throughout 1951: Flake, 77–80 percent, paper bags, carlots, works, freight equalized, $25 per ton; liquor, same basis, 40 percent, tank cars, $10.50 per ton; pellets, bags, carlots, works, $31.25 per ton; solid, 73–75 percent, drums, carlots, freight equalized, $23.50 per ton.

BROMINE

Sales of bromine and bromine compounds during 1951 were at the highest level in history. At the end of World War II, sales dropped drastically and then began a steady increase. The principal use for bromine is as ethylene dibromide in gasoline antiknock additive. The number of automobiles on the Nation's highways is increasing each year, and motorists are demanding more and better gasoline. This, in turn, is increasing the demand for antiknock fluid. Expanding airplane production and air-miles flown are increasing the quantity of high-grade gasoline being burned. More bromine is being used in fumigating soils, grains and other foods, and food-processing equipment. An unlimited reserve supply of bromine is available in seawater and natural brines, and domestic producers are expanding production facilities.

In the United States the largest producer, Ethyl-Dow Chemical Co., recovers bromine from seawater at Freeport, Tex. A second seawater plant is operated by Westvaco Chemical Division of Food Machinery & Chemical Corp. in the San Francisco Bay area. The following firms recover bromine from well brines in Michigan: The Dow Chemical Co., Midland, second largest producer in the United States, Great Lakes Chemical Corp. at Filer City, Michigan Chemical Corp. at St. Louis, and Morton Salt Co. at Manistee. Pomeroy Salt Co. at Minersville, Ohio, and Westvaco Chemical at South Charleston, W. Va., also treat well brines. American Potash & Chemical Corp. recovers bromine from the brine of Searles Lake in California.

TABLE 3.—Bromine and bromine in compounds sold or used by primary producers in the United States, 1946–51

Year	Pounds	Value	Year	Pounds	Value
1946	42,780,925	$8,560,434	1949	88,725,709	$16,267,908

Total	116,418,817	98,502,300	18,794,978	152,390,081	129,563,073	26,179,556

[1] Calculated as theoretical bromine content present in compound.
[2] Also includes some bromine used to make other products than those listed below. Before 1951 this quantity was excluded.

According to Oil, Paint and Drug Reporter, prices for bromine and the principal bromine compounds were unchanged throughout 1951. Purified bromine in cases, freight allowed, east of the Rockies or in lead-lined drums delivered, was quoted at 25 cents per pound. Potassium bromide, U. S. P., was quoted at 34 to 37 cents per pound and sodium bromide, U. S. P., at 34 to 35 cents per pound.

IODINE

Iodine was produced in the United States by Dow Chemical Co. and Deepwater Chemical Co., Ltd., from waste oil-field brines in California. The Bureau of Mines does not publish the figure on domestic production to avoid disclosure of individual company operations.

Digitized by Google

For many years Chile has been the world's most important source of iodine. In the Provinces of Antofagasta and Taropaca iodine occurs principally as the mineral lautarite associated with the nitrate deposits. Chile Nitrate Sales Corp., sales agent for producers in Chile, imported 667,426 pounds of iodine into the United States during the year. This organization maintains large stocks in New York City for rapid distribution to consumers in this country.

In Japan, iodine is recovered from seaweed and brine. In 1951 184,681 pounds of iodine was imported from Japan. This source developed since World War II and shipped increasing quantities each year.

These three sources—domestic, Chile, Japan—supplied all United States requirements.

It was reported that a water-sterilization tablet containing triglycine hydroperiodide. recently tested in Korea, was more effective against cysts responsible for amoebic dysentery than those containing other halogens as the active ingredient.[5]

TABLE 5.—Crude iodine consumed in the United States in 1950–51

Compound manufactured	1950			1951

TABLE 6.—Crude iodine imported for consumption in the United States, 1946–51

[U. S. Department of Commerce]

Year	Pounds	Value	Year	Pounds	Value
1946	886,578	$976,190	1949	489,999	$719,758
1947	2,260,506	2,756,888	1950	724,858	1,055,946
1948	592,136	847,752	1951	852,107	1,320,328

The many uses for radioactive iodine (I^{131}) were reviewed.[6]

Iodine 132 (I^{132}) is reported to have been made available on a commercial basis. This material has a half-life of 2.4 hours and may prove valuable in medical and biological studies.[7]

The physical properties of over 500 inorganic iodine compounds were listed by the Chilean Iodine Educational Bureau, Inc., 120 Broadway, New York 5, N. Y.[8] Much additional information on the subject of iodine is available from this organization.

According to Oil, Paint and Drug Reporter, the price of crude domestic iodine at the beginning of 1951 was $1.70 per pound. In February it was quoted at $1.70 to $1.90 per pound; in November, at $1.70 to $2.04 per pound; in December, at $1.84 to $2.04.

SODIUM COMPOUNDS

Sodium Carbonate.—Soda ash is a basic chemical and a good indicator of industrial activity. The shortage of soda ash during 1950 hampered many industries and was carried over into the early part of 1951 as consumers attempted to replenish inventories depleted the previous year. However, later in 1951 demand lessened, the backlog of orders was reduced, and by the end of the year deliveries were being made on request.

Sales of natural soda ash—only a small percentage of total soda-ash production—were virtually the same as in the previous year. This natural material is produced in California largely for use on the west coast. Only during periods of shortage has it been able to compete in the East with the manufactured product.

Sales of natural soda ash were reported by the following producers in California in 1951: American Potash & Chemical Corp., 3030 W. 6th St., Los Angeles 54, Calif., on Searles Lake; Columbia-Southern Chemical Corp., subsidiary of Pittsburgh Plate Glass Co., Bartlett, Calif.; Kaiser Aluminum & Chemical Corp., 1924 Broadway, Oakland 12, Calif., on Owens Lake; Natural Soda Products Co., 405 Montgomery St., San Francisco 4, Calif., plant at Keeler, and West End Chemical Co., 608 Latham Square Building, Oakland 12, Calif., plant at Westend.

Outside California, natural sodium carbonate is produced only near Green River, Wyo. In this area, trona (hydrous sodium carbonate) occurs as a bedded deposit at a depth of about 1,500 feet. A considerable tonnage of trona has been produced from these deposits in the past few years. In 1951 Westvaco Chemical Division of Food Machinery & Chemical Corp. began to expand its mining facilities and to construct new refining facilities with a reported capacity of 300,000 tons of refined soda ash annually.[9]

TABLE 7.—Manufactured sodium carbonate produced [1] and natural sodium carbonates sold or used by producers in the United States, 1947–51

Year	Manufactured soda ash (ammonia-soda process) [2]	Natural sodium carbonates [3]

According to Oil, Paint and Drug Reporter, the price of soda ash was unchanged throughout 1951 at $1.30 per 100 pounds dense ash, 58 percent, bulk, carlots, works, and $1.20 per 100 pounds for light ash, same basis.

The consumption pattern of sodium carbonate, as estimated by Chemical Engineering, is shown in table 8.

TABLE 8.—Estimated consumption of sodium carbonate in the United States 1947–51, by industries, in thousands of short tons

Sodium Sulfate.—Increasing demands for sodium sulfate from the kraft pulp and glass industries created a tight supply situation in the first part of 1951. However, production was increased, demand leveled and, by the end of the year, suppliers were able to make prompt shipments.

Much of the sodium sulfate produced in the United States is a co-product or byproduct in the manufacture of hydrochloric acid, rayon, and several other products. However, a considerable tonnage is recovered from natural deposits. The following firms reported production from natural sources in 1951: American Potash & Chemical Corp., 3030 W. 6th St., Los Angeles 54, Calif., on Searles Lake; Iowa Soda Products Co., P. O. Box 476, Council Bluffs, Iowa, plant at Rawlins, Wyo.; Ozark-Mahoning Co., P. O. Box 449, Tulsa 1, Okla., plant at Monahans, Tex.; and Wm. E. Pratt, P. O. Box 738, Casper, Wyo.

The Bureau of Mines issued a report of an investigation of sodium sulfate deposits at Bull Lake in Carbon County, Wyo.[10] Bull Lake is one of several saline lakes situated a few miles north of Rawlings, Wyo. Drilling in the lake totaled 512 feet. Saline beds were found in thicknesses up to 26 feet. Some samples contained over 50 percent sodium sulfate.

According to Oil, Paint and Drug Reporter, salt cake, bulk, works, was quoted unchanged at $17 per ton throughout the year. Glauber's salt, anhydrous, crystalline, bags, carlots, works, freight allowed, was quoted at $45 per ton. Anhydrous sodium sulfate, technical grade, bags, carlots, works, was quoted at $2 per 100 pounds.

Sodium Metal.—In response to increased demands, domestic sodium-metal production capacity has been greatly expanded, and further expansions were planned. Increased production of tetraethyl-lead gasoline antiknock compound and synthetic detergents have been important factors in the greater demand.

Most of the present sodium production is by the electrolysis of a mixture of salt (NaCl) and calcium chloride in a Downs cell. There are three domestic producers: National Distillers Chemical Corp., Ashtabula, Ohio; E. I. du Pont de Nemours & Co., Inc., Niagara Falls, N. Y.; and Ethyl Corp., Baton Rouge, La.

In 1951, 118,904 short tons of sodium metal was produced in the United States, according to the United States Bureau of the Census.

National Distillers Chemical Corp. offered commercially a sodium-calcium mixture, normally recycled in its process. This product contains 65 to 75 percent sodium by weight and 15 to 25 percent calcium.[11] This firm also issued a booklet entitled "Handling Metallic Sodium," which contains helpful information on safe handling methods used in commercial operation.

Oil, Paint and Drug Reporter quoted prices of sodium in 1951 as follows: In tanks, works, 16 cents per pound; in bricks, drums, works, 17 to 18 cents per pound until March, 17 to 19 cents per pound to the end of 1951.

BORATES

The high level of industrial activity during 1951 created an unprecedented demand for boron compounds; as a result, a new production record was established for this important industrial raw material.

Production of boron-treated steels was growing rapidly, and interest continued unabated during 1951. It was estimated that by the end of 1951 as much as 15 to 20 percent of the alloy steel produced in the United States contained boron.[12]

A number of articles were published in which the background of boron steels was reviewed, technical details were presented, and applications and performance were discussed.[13]

Salt

By Florence E. Harris and F. M. Barsigian

GENERAL SUMMARY

PRODUCTION of salt in the United States reached an extraordinarily high level in 1951, chiefly under the stimulus of increased chemical requirements. The total output of 20.2 million short tons valued at $69.7 million showed a quantity gain of 22 percent and a value gain of 16 percent over 1950. Outstanding features were the 2½-million increase in the output of salt in brine, which was 27 percent greater than in 1950, and the gain of about three-fourths of a million tons, or 19 percent, in sales of rock salt. Evaporated-salt production gained 10 percent.

TABLE 1.—Salient statistics of the salt industry in the United States.[1] 1947–51

	1947	1948	1949	1950	1951
Sold or used by producers:					
Dry salt:					
Evaporated (manufactured)...short tons..	3,158,718	3,207,403	3,284,361	3,329,288	3,654,808

Value.....	$9,159,067	$7,900,855	$7,670,015	$8,115,615	$11,309,978
Total salt:					
Short tons.....	16,053,882	16,403,293	15,572,215	16,629,809	20,207,131
Value [2].....	$52,191,688	$54,331,782	$53,626,238	$59,911,343	$69,735,000
Imports for consumption:					
Short tons.....	1,909	5,621	6,309	7,869	4,329
Value.....	$22,893	$40,748	$60,605	$58,819	$46,831
Exports:					
Short tons.....	[3] 188,307	387,601	359,776	190,377	439,114
Value.....	[3] $1,588,847	$5,930,170	$3,353,115	$1,776,062	$3,501,904
Apparent consumption [4].....short tons..	[3] 15,771,005	16,021,313	15,218,748	16,447,301	19,772,346

[1] Includes Puerto Rico.
[2] Values are f. o. b. mine or refinery and do not include cost of cooperage or containers.
[3] 96,479 short tons valued at $2,347,679, shipped under the U. S. Army Civilian Supply Program, is excluded from exports shown but is deducted from apparent consumption.
[4] Quantity sold or used by producers, plus imports, minus exports.

Exports, largely to Japan and Canada, increased to nearly 440,000 tons, but imports declined to only 4,300 tons.

World production of salt was estimated at about 53.5 million metric tons.

Figure 1 shows that the output of the salt industry has been advancing more rapidly than general industrial production.

PRODUCTION

PRODUCTION BY STATES

Requirements of the defense production programs and a general advance in industrial activity stimulated production of salt in 1951. Output increased in all salt-producing States, and production facilities were expanded in most of them in 1951. Of the 1951 total, five States—Michigan, New York, Ohio, Louisiana, and Texas—supplied nearly 84 percent.

Accomplishments in 1951 by States follow.

Alabama.—Although no salt was produced in Alabama in 1951, the Mathieson Chemical Corp. began construction of the plant of its subsidiary, the Mathieson Alabama Chemical Corp., to supply salt from brine wells within the State for the manufacture of chlorine and caustic soda in 1952. Construction of the $11 million plant was begun in the late spring of 1951. The company will obtain the salt from the McIntosh salt dome about 40 miles north of Mobile.

[1] Less than 0.5 percent.
[2] Includes Nevada, New Mexico, Oklahoma, and Virginia.

California.—Production of salt was greatly accelerated in 1951 as a result of augmented demands by the chemical industry and the Japanese market. The Leslie Salt Co. formed a subsidiary company, the Leslie Terminal Co., to operate the dock and ship-loading facilities at Redwood City. The first ship was loaded late in March 1951. During 1951 evaporating and crystallizing ponds and a washing plant were being built near the terminal, but no yield was expected from these new ponds for several years. The salt loaded at the new dock was brought by rail from the operations at Newark and Alvarado.[1] In 1951 the Metropolitan Water District of Southern California concluded experiments at Dale Lake and was awaiting action on its application to lease about 1,840 acres of salt-bearing land on the public domain from the United States Department of the Interior. The water district has been obtaining its salt for water softening from the Bristol Lake operations of the California Salt Co.[2]

Kansas.—To improve the production of certain grades of salt in Kansas, a study was made, and the results were published in 1951.[3]

Louisiana.—Although it did not affect the 1951 production of salt, the Solvay Process Division of Allied Chemicals and Dye Corp. began a $13 million 2-year construction program at Baton Rouge, La., designed to expand its soda-ash plant capacity by one-third.[4]

Michigan.—International Salt Co. rock-salt mine 1,100 feet under Detroit, Mich., was described.[5] This is the only rock salt mine in the State; all other production is from wells. In the preparation of salt for marketing, the Manistee Iron Works Co. has developed a small

Digitized by Google

packaged-salt plant, which is said to employ radically improved methods of heat recovery.[6]

New York.—The Solvay Process Division, Allied Chemical and Dye Corp., in June 1951, announced plans to construct a new mercury-cell chlorine-caustic soda unit at its plant near Syracuse. The new $10 million plant would double the capacity of Solvay's chlorine-producing facilities at Syracuse. It was estimated that it would require 1½ to 2 years to complete the project. Solvay has large salt reserves.[7]

Ohio.—International Salt Co., Inc. (headquarters, Scranton, Pa.), continued to search for a large salt deposit near Ashtabula, Ohio. The company's drilling on a tract near Strongsville was described.[8]

Texas.—The new Kleer mine of Morton Salt Co., which replaced the old mine at the same site at Grand Saline, Tex., and had been functioning for 1½ years and the new evaporating plant for refining salt by the vacuum and grainer methods were described in a 1951 article.[9] The marketing of brine by the Texas Brine Corp. at Houston was described. This company obtains its salt from its affiliate, United Salt Corp., the brine from a dome 5 miles from Houston, and the rock salt from Hockley, Tex. The saturated brine is delivered in trailer tank trucks with a capacity of 2,000 to 4,000 gallons of brine (5,300 to 10,600 pounds of salt) to customers within a radius of 250 miles from Houston. Cost of brine to customers who use it in paper mills, synthetic-rubber plants, electrolytic caustic units, water-softening plants, oil operations, and ice and refrigeration plants, is on the basis of salt content.[10]

West Virginia.—In mid-1951 the Pittsburgh Plate Glass Co. announced plans for an $8½ million expansion of facilities to produce chlorine and caustic soda at the Natrium plant operated by its subsidiary, the Southern Alkali Corp. Salt for manufacturing these chemicals was to be obtained from the brine wells of Pittsburgh Plate Glass Co. at the site.[11]

In April 1951 the Southern Alkali Corp. became a wholly owned subsidiary of the Pittsburgh Plate Glass Co. The parent company subsequently transferred its Columbia Chemical Division to Southern Alkali Corp., which then operated plants producing chlorine, alkali, and related chemicals based on salt at Barberton, Ohio, Natrium, W. Va., Corpus Christi, Tex., Lake Charles, La., and Bartlett, Calif.[12] The Solvay Process Division expanded facilities for producing salt because of increasing demands for chlorine at Hopewell, Va. The process used to produce chlorine and caustic was described.[13]

[2] Includes California, Nevada, New Mexico, Oklahoma, Texas (as indicated by footnote 1 above), Utah, and West Virginia.

Rock Salt.—Shipments of rock salt reported from 18 mines in 8 States increased 735,000 tons in 1951 over 1950. Rock-salt production for many years has centered in the North and South Central States.

TABLE 5.—Rock salt sold by producers in the United States, 1946–51

Year	Short tons	Value	Year	Short tons	Value
1946	3,412,008	$13,308,001	1949	3,444,341	$16,232,479
1947	3,754,353	15,989,680	1950	3,927,267	19,435,431
1948	3,846,846	16,970,742	1951	4,662,194	23,589,552

Pressed Blocks.—In 1951 pressed blocks were made from evaporated salt in 22 plants and from rock salt in 8 plants in 8 States. The first and largest use for pressed blocks is for cattle. A new application in 1951 was the substitution of pressed blocks for bags of salt in cooling systems. The salt blocks dissolve at the proper rate, and the nuisance of lint from the bags is avoided.

TABLE 6.—Pressed-salt blocks sold by original producers of the salt in the United States, 1947–51

Year	From evaporated salt		From rock salt		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1947	260,399	$2,708,857	69,163	$638,958	329,562	$3,347,815

Salt in Brine.—In response chiefly to the rising demand for chlorine and soda ash, facilities for the production of salt in brine were expanded greatly. Output of salt in brine totaled 11,890,000 short tons in 1951 compared with 9,373,000 tons in 1950. It was 59 percent of total salt production in 1951, compared with 56 percent in 1950.

CONSUMPTION AND USES

Table 7 shows domestic consumption primarily. The largest use of salt was for the manufacture of soda ash—41 percent of the total in 1951. In addition, most of the salt exported to Japan apparently was used for manufacturing soda ash. The next important use was for chlorine and chlorine compounds—23 percent. Expansion programs were adopted by most of the chemical companies producing these salt derivatives.

Increases, although on a smaller scale, were noted for highways, ice control, "other chemicals" (*see* table 7), livestock and agriculture, water treatment, canning, meat packing, and metallurgy—including metallic sodium production.

Minor decreases occurred in use of salt in dyes and organic chemicals, hides and leather, and table and other household uses.

Digitized by Google

The "Undistributed" item in table 7 includes a number of miscellaneous uses of all three types of salt. Following are some of the more important applications of the "Undistributed" salt in 1951.

About 130,000 tons of salt (exclusive of chlorine and other salt derivatives so used) was employed in the manufacture of rubber. This was 80,000 tons more than in 1950. About 52,000 tons was used in making pulp and paper, an advance of 17,000 tons over 1950. Other uses included sales to State and Federal Governments and to industry for brick and tile and in making glass, explosives, oil-well drilling, pharmaceuticals, petroleum refining, and vegetable-oil refining.

[2] Revised figure.
[3] Data for salt in brine included with "Undistributed" to avoid disclosure of individual company operations.
[4] Livestock salt is about 90 percent of the total.
[5] Comprises miscellaneous uses and uses for which data may not be shown separately (*see* footnotes 1 and 3); also includes some exports and consumption in Territories and possessions.

Geographical Distribution.—Salt is transported from the areas of production to consumers by rail, truck, boat, and pipeline. The dry salt is shipped by the first three methods exclusively. Brine is transported to refineries and chemical plants chiefly by pipelines ranging from a few feet to as much as 60 miles in length. An innovation in recent years has been the haulage and delivery of brine by trailer tank trucks in Texas, mentioned under Production by States.

Primary shipments of salt to various States by the producers are shown in table 8.

PRICES

Prices quoted at works by the Oil, Paint and Drug Reporter, for salt, throughout 1951 are shown in table 10.

TABLE 10.—Price of bagged salt, at works, in 1951, per 100 pounds

[Oil, Paint and Drug Reporter]

Rock salt:	
Paper bags, carlots	$0.94
Burlap bags, carlots	1.09
Paper bags, less than carlots	1.15
Burlap bags, less than carlots	1.30
Table, vacuum, common fine, bags:	
Carlots	1.09
Less than carlots	1.20

FOREIGN TRADE [15]

Imports of salt in 1951 were about half those in 1950, whereas exports of salt more than doubled.

Imports.—Almost all of the salt imported in 1951 was from Canada; 69 percent was packaged.

Exports.—In 1951 exports of salt were over twice as large as in 1950, chiefly because of large shipments to Japan compared with only a few tons in 1950. Salt exports to Canada increased about 30,000 tons. In 1951 total salt exports of 439,100 short tons represented a new all-time high record, superseding that of 387,600 tons in 1948.

[15] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Digitized by Google

Of the salt exports in 1951, 47 percent by tonnage and 35 percent by value was shipped to Japan, 45 percent by tonnage and 44 percent by value to Canada, and the remainder to more than 30 other countries.

The difference in the values given reflects the fact the material shipped to Japan was chiefly crude salt for industrial uses and that shipped to Canada was high-grade salt.

WORLD REVIEW

In 1951 the output of salt increased in most of the large and many of the small producing countries. Overall world production was 5 million tons greater in 1951 than in 1950. The United States produced roughly one-third of the recorded world output shown in table 14. All tonnages in this section are metric, unless otherwise specified.

NORTH AND CENTRAL AMERICA

Canada.—Apparent consumption of salt in Canada was about 1,103,500 tons in 1951.[16] The largest imports were those of salt in bulk, all from the United States. Effective April 1, 1951, Canadian Industries, Ltd., and Alberta Salt Co. were consolidated as the Canadian Salt Co. Brands such as Windsor and Cascade salt were to be marketed by the company. The Salt Division of Canadian Industries, Ltd., had a plant at Neepawa, Manitoba, originally built by the Neepawa Salt Co. in 1930. The Windsor plant of Canadian Industries and Neepawa plant, together with the plant of the Alberta Salt Co. at Lindbergh, Alberta, constituted the holdings of the new company.[17] A mineral survey in Nova Scotia in 1951 revealed the presence of a large deposit of salt, above and adjacent to which was a deposit of high-grade limestone. With a nearby fuel source in the Sydney, Nova Scotia, coal fields the situation was regarded as favorable for a soda-ash industry in the vicinity of Antigonish Harbor.[18]

Cuba.—Production of salt, estimated to have increased to 63,500 metric tons in 1951, was valued at $2,500,000.

Dominican Republic.—Following a bond issue of 3,000,000 pesos in 1950, orders were placed for modern equipment in the mechanization of the salt and gypsum deposits taken over by the Government Agricultural and Industrial Credit Bank. Underground development included 6 exploratory tunnels, from 2 of which rock salt was being extracted in 1951. Narrow-gage railroad cars transport the salt as mined to crushers on the same level, thence to open concrete storage bins awaiting loading into railroad cars on the main track to the port of Barahona, 25 miles east of the mine. A new wharf was constructed for handling salt exports. Two mobile diesel-electric cranes had been ordered for loading the salt on large vessels. Reserves were estimated by the engineer in charge at about 250 million metric tons, and it was expected that full-scale production would be at the rate of 1,000,000 tons annually. Reportedly a market for Dominican rock salt had been found in Japan, and large shipments would be made thereto when full-scale operation was reached, probably late in 1952.

Guatemala.—Production of sea salt, which had decreased slightly in 1950 because foreign prices were so much lower than domestic, increased somewhat in 1951. Some interest was shown in finding and exploiting new deposits of rock salt. However, no progress was evident and Guatemala continued to rely on sea salt, supplemented by imports.[19]

Netherlands Antilles.—Bonaire was the only one of this group of islands that supplied salt in 1951. Output data were not available, but exports totaled 474 tons gross weight valued at 73,492 Curaçao florins (about $19,300).

Panama.—Output of sea salt (the only source) in 1951, reported by the Agricultural, Livestock, and Industrial Banco, which is in charge of production and distribution, was about 50 percent greater

than in 1950. Previously limited to 10 quintals (about 1,100 pounds) per deposit, the bank removed the restriction in 1951 because of floods caused by heavy rains. The 1952 production was to be limited to 5 quintals per deposit (beach area).[20] The bank expected to purchase the entire output at $1.50 per quintal.

SOUTH AMERICA

Brazil.—Production of Brazilian sea salt for 1950, figures for which became available at the end of 1951, increased about 75,000 tons. The project of installing a caustic soda plant based on local salt as the raw material was still in the planning stage at the end of 1951.

Venezuela.—There were no further developments in the project of establishing a plant in Venezuela to produce chlorine and caustic soda from local salt.

EUROPE

Austria.—Salt produced in 1951 included 94,838 tons of evaporated salt and 267,456 tons of salt content of brine (871,353 cubic meters). Although output of evaporated salt was 4 percent over the 1950 output and 118 percent of the 1937 level, it was below the peak war year 1940, when 108,719 tons was produced. Rock-salt output was insignificant.

Denmark.—All of the salt consumed in Denmark was imported. The deposits discovered in 1946 had not been developed. The broad details of salt consumption, imports and exports were given in a recent report.[21]

Germany, West.—The rate of production of dry salt—both rock and evaporated—increased so much in 1951 that a new postwar record was established.

Italy.—The salt industry of Italy, said to be the most highly developed of its kind in Europe, was described in a report.[22] Production, by the State Monopoly and by private concessions, has been from three sources; in order of their importance these were: Sea water, rock-salt deposits, and salt springs.

Spain.—Output of salt increased and exports more than doubled in 1951. Of the 355,193 tons exported valued at 4,478,000 gold pesetas (1 gold peseta, as a customs unit, in 1951 equaled about $0.3267 or 3.577 paper pesetas), Japan was supplied with 226,424 tons valued at 2,538,000 pesetas (28,296 tons at 287,000 pesetas in 1950), and Iceland ranked next with 35,800 tons valued at 541,000 pesetas (33,228 tons at 535,000 pesetas in 1950). The remainder was shipped to 13 other countries.

ASIA

Aden.—Production costs of salt in Aden in summer and winter were reported in 1951.[23]

Afghanistan.—As with all Afghan mineral resources except talc, salt mining is done by the Afghan Ministry of Mines, which realizes a considerable profit from it. Salt output in 1951 was from rock-

salt works at Taliqan and Khalifghan; salt lakes at Andkhoi, Mazar-i-Sharif, Herat, and Mukur; salt wells at Kandahur; and salt springs at Ghorband. Studies had been made of modern methods of producing and marketing salt, but the Ministry had no definite plans for modernization of mining. Hand methods of mining salt in quarries and around lake shores were as primitive as when the deposits were first worked. The output was for domestic demand, and no large stocks were maintained.

India.—Production of salt in India was somewhat higher in 1951 than in 1950; and there were no imports, although 139,300 tons was imported in 1950. The Indian press stressed that, for the first time in 100 years, India achieved self-sufficiency in salt production. Output was expected to increase in 1952 so that substantial quantities could be exported. Japan offered market possibilities. The Ministry of Production reported rapidly increasing manufacture on the west coast, where salt of superior quality was being processed. Six new salt works were licensed in 1951. Cooperative organizations have been encouraged and from these and other unlicensed small manufacturers salt output increased from 48,518 tons in 1950 to 93,303 tons in 1951. On advice of an advisory committee, the Government of India decided that no salt should be released for human consumption in 1951 if its sodium chloride content was below 92 percent. The Government also decided that the standard for edible salt should be raised to 94 percent sodium chloride in 1952 and to 96 percent in 1953, the minimum content prescribed by the Indian Standards Institute.[24] In November 1951 the Council of Scientific and Industrial Research of India approved proposals to establish a research station at Sambhar Lake (Rajasthan) "to conduct investigations to improve the salt manufacturing process in the use and recovery of chemicals therefrom." [25]

Iran.—The output of salt in Iran is entirely rock salt from mines in most instances leased to private companies. As production is inadequate, some salt has to be imported. The industry was described recently.[26]

Japan.—Salt was needed by Japan for restoration of its large chemical industry, and research and experimentation were continued on methods of recovering industrial salt from sea water to compensate for lack of former supplies from China. Large quantities of salt have had to be imported. Japan's buyers searched the world for supplies, and much larger tonnages were obtained in 1951 than in 1950, chiefly from Egypt, Spain, Aden, and the United States, and some from Italy and India.

Pakistan.—A Sea-Salt Control Order (issued November 30, 1950) gave the Government's sea-salt controller complete control of the sale, stocking, and distribution of sea salt.[27] It was reported that the salt shortage in East Pakistan ended in November 1951.[28]

Taiwan (Formosa).—Salt production, marketing, and problems peculiar to the Taiwan salt industry were discussed in an abstract based on the Report on Survey of Taiwan Salt Production and Distribution, by the Mutual Security Agency Mission to China, covering 1946 to 1951, inclusive.[29]

Turkey.—The Monopolies Administration planned to increase salt production 200,000 tons by 1953 as a result of the installation of new equipment and other improvements at the salt mines of Camalti and Yavsan.

AFRICA

Angola.—Domestic consumption of salt in Angola increased slightly from 1949 to 1951, chiefly because of installation of new fish-processing plants. About 75 percent of Angola's salt was produced in the vicinity of Lobito by 6 enterprises, which processed and marketed through a quasi-governmental association.[30]

Belgian Congo.—The output of salt in Belgian Congo in 1951 was under 1,000 tons, of which about 62 percent was from the Katanga area. Belgian Congo and Ruanda-Urundi imported about 30,000 tons valued at 48,783,000 Belgian francs in 1950, of which about 25 percent came from Angola and the remainder from other countries.[31]

Egypt.—According to the American Embassy, Cairo, production of salt in Egypt is governed by foreign demand. Of the 607,000 tons reported produced in 1951, 346,882 tons was exported. Exports to Japan increased from 16,898 tons valued at $61,934 in 1950 to 149,252 tons valued at $480,304 in 1951. The largest producing company, the Société Egyptienne pour l'Exploitation des Salines de Port Said, S. A. E., was formed in 1950 with a 20-year concession to take over the activities of the former Port Said Association, Ltd. In 1951, 305,631 tons was produced by the Port Said firm. The second largest producer was the National Salt & Mining Co., Ltd., which held salt concessions at Mex, Alexandria, and Baltim in the Middle Delta. Production in 1951 by this company was 249,062 tons, of which 236,587 tons was from Mex. Also, limited operations were carried out by three other concessionnaires with outputs of 50,000, 2,000, and 340 tons, respectively. In addition to the foregoing licensed concessions, in the Damietta area a great number of individually owned solar salt beds of small area produced an aggregate output estimated at 40,000 tons not included in official production statistics.

Sand and Gravel

By Henry P. Chandler and Nan C. Jensen

GENERAL SUMMARY

PRODUCTION of sand and gravel in the United States in 1951 surpassed all previous records. The combined tonnage of these commodities increased 8 percent and the value 13 percent compared with 1950. The value of sales was approximately one-third of a billion dollars. All classifications except filter sand and noncommercial paving gravel gained over 1950. In commercial operations gains were substantial in almost every category, while in the Government-and-contractor operations the largest tonnage increases were reported under paving sand and building gravel. The output of sand was 37 percent and that of gravel 63 percent of the combined domestic production of these commodities during 1951, the same proportions as in 1950.

In this chapter the terms "production" and "sales" (sold or used by producers) are used interchangeably, inasmuch as stocks of sand and gravel are relatively small, and fairly constant from year to year.

DOMESTIC PRODUCTION

A production of 401,620,000 tons of sand and gravel recorded for 1951 represents an alltime high for the industry. Its value at the pit was $333,826,000. The quantity produced was 8 percent higher than in 1950 and the value 13 percent higher. These increases reflected the high level of construction activity throughout 1951.

In 1951 California was the largest producer, followed by Michigan, New York, Illinois, Ohio, Wisconsin, Texas, Minnesota, and Pennsylvania, in the order named. These 9 States, each with an output exceeding 15 million tons, accounted for 51 percent of the total production.

Tables 3 and 4 show details of production by States and uses in 1951.

TABLE 2.—Sand and gravel sold or used by producers in the United States,[1] 1947–51

Year	Sand		Gravel (including railroad ballast)		Total	
	Quantity (thousand short tons)	Value (thousand dollars)	Quantity (thousand short tons)	Value (thousand dollars)	Quantity (thousand short tons)	Value (thousand dollars)
1947	108,719	94,154	178,940	122,715	287,659	216,869
1948	118,661	107,915	200,605	144,583	319,266	252,498
1949	117,036	105,489	202,068	142,954	319,104	248,443
1950	138,900	126,311	231,555	168,729	370,455	295,040
1951	150,376	145,200	251,244	188,626	401,620	333,826

[1] Includes Alaska, Hawaii, and Puerto Rico.

Government-and-Contractor Production.—As indicated in figure 2, the output of sand and gravel from noncommercial or Government-and-contractor operations in 1951 was 29 percent of the total tonnage compared with 30 percent in 1950 and 28 percent in 1949. The value of this output was 16 percent of the total dollar value of production compared with 18 percent in 1950.

DEGREE OF PREPARATION

A large proportion of the output of commercial sand and gravel plants (89 percent in 1951), consists of prepared material, whereas Government-and-contractor production is chiefly an unprepared or bank-run product. As indicated in table 7, the latter group of producers used 61 percent of its output in unprepared form in 1951. The table shows that the relationship in both groups in 1951 varied in small degree from those of 1950.

SIZE OF PLANTS

The average plant output of commercial operators, except railroad plants, was about 120,000 short tons in 1951 compared with 101,000 in 1950 and 92,000 in 1949. Plants producing between 100,000 and 200,000 tons in 1951 supplied 20.1 percent of the total output. As in other recent years, this is the most productive group of plants. The number of small plants producing under 25,000 short tons decreased from 890 to 759, and those producing 25,000 to 50,000 tons decreased from 478 to 381. The trend toward larger producing units continued in 1951, when the number of plants with an output of over 1,000,000 tons increased from 22 to 27, with a total increase in output for this group exceeding 10,000,000 tons. Details of output, by size groups, are shown in table 8.

TABLE 8.—Comparison of number and production of commercial sand and gravel plants in the United States, 1950–51, by size group [1]

Size group, in short tons	1950				1951

1,000,000 and over	22	.9	33,347	13.2	27	1.2	43,953	15.7
Total	2,500	100.0	252,381	100.0	2,338	100.0	280,315	100.0

[1] Excludes operations by or for States, counties, municipalities, and Federal Government agencies as follows—1950: 835 operations with an output of 112,899,000 tons of sand and gravel; 1951: 750 operations, 115,801,000 tons. Excludes operations by or for railroads as follows—1950: 142 operations with an output of 5,175,000 tons of sand and gravel; 1951: 131 operations, 5,504,000 tons. Includes Alaska.

[2] Includes a few companies operating more than 1 plant but not submitting separate returns for individual plants.

METHODS OF TRANSPORTATION

Of the total output of sand and gravel in 1951, 41 percent was moved by truck from commercial plants. Assuming the entire output of Government-and-contractor operations to be moved by truck, 70 percent of the domestic sand and gravel output was so transported, compared with 71 percent in 1950. Railroads carried 20 percent, the same as in 1950. Shipments by waterway, a method important in a few areas, remained at 6 percent, and unspecified transportation increased from 3 to 4 percent. As shown in table 9, at least 90 percent of the total tonnage shipped (commercial and Government-and-contractor) moved by truck or rail.

[1] Includes Alaska, Hawaii, and Puerto Rico.
[2] Entire output of Government-and-contractor operations assumed to be moved by truck.

EMPLOYMENT AND PRODUCTIVITY

The total number of men employed in the sand and gravel industry in the United States during 1951 averaged about 27,000 compared with about 26,000 in 1950. The average number of days worked increased from 238 to 241. The average number of hours per man per day was the same in 1951 as in 1950, but the output per man per shift increased from 41 to 43.9 short tons. The highest production per man per shift was in the Michigan-Wisconsin area, followed in order by New York, California-Nevada, and the North Dakota-South Dakota-Minnesota areas. Table 10 gives a breakdown of employment and production of commercial sand and gravel plants, by regions.

CONSUMPTION

Sand and Gravel for Construction.—The demand for sand and gravel by the construction industry in 1951, as indicated by shipments from commercial plants, continued the upward trend that characterized 1950. Building sand sales increased 5 percent, paving sand 12 percent, building gravel 10 percent, and paving gravel 15 percent. These increases reflect an accelerating activity in building.

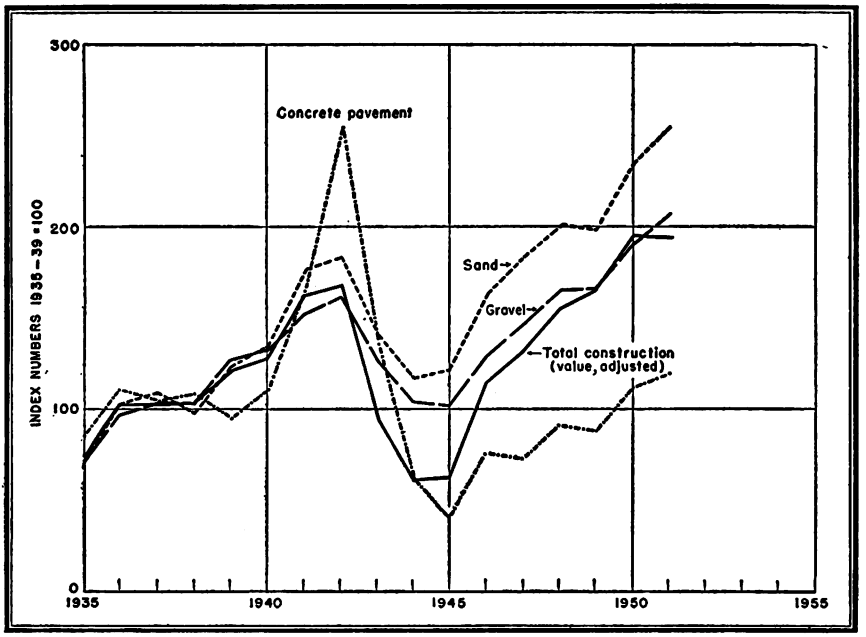

FIGURE 3.—Quantity of sand and gravel produced compared with total construction (value, adjusted to 1939 prices), and concrete pavements (contract awards, square yards) in the United States, 1935–51. Data on construction from Statistical Abstracts of the United States, and on pavements from Survey of Current Business.

Industrial Sands.—The output of nearly all classes of industrial sands increased in 1951: Molding sand 12 percent; glass sand 7 percent; grinding and polishing sand 14 percent; fire and furnace sand 26 percent; and engine sand 10 percent. Such advances were to be expected because of the high level of industrial activity. Sales of filter sand, however, declined 27 percent.

Digitized by Google

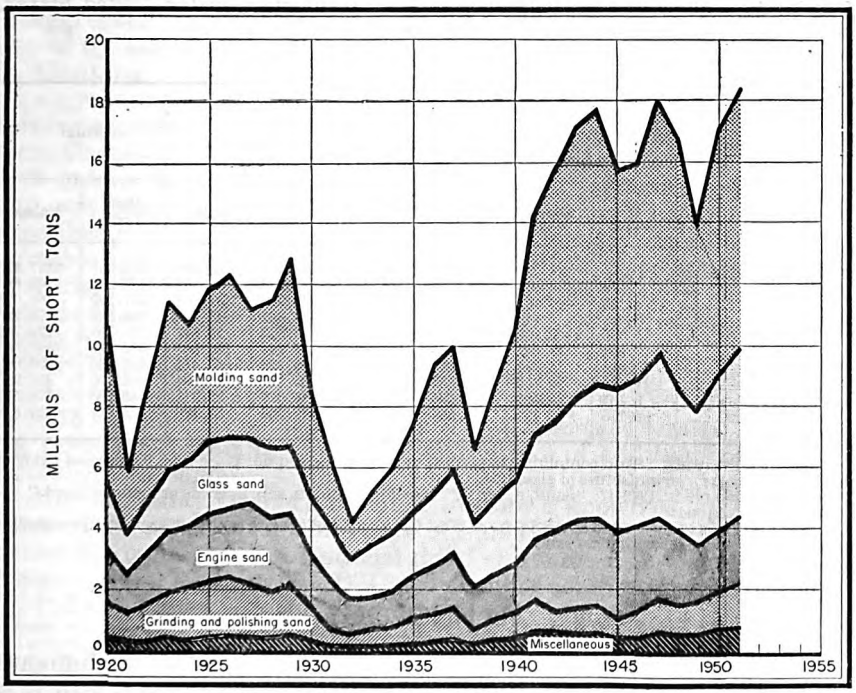

FIGURE 4.—Production of industrial sands in the United States, 1920–51.

PRICES

The average value for all shipments of sand and gravel in 1951, commercial and Government-and-contractor operations combined, increased 4 percent over the 1950 average. Moderate gains in unit values were recorded for most of the uses, but the increases for fire and furnace, filter, and railroad ballast sand ranged from 19 to 24 percent. The value per ton of total Government-and-contractor sales declined 4 percent.

FOREIGN TRADE [1]

Imports of sand and gravel in 1951 (omitting glass sand) were 8 percent greater in quantity and 18 percent higher in value than in 1950. Belgium furnished all but a small part of the glass sand, while Canada supplied 314,105 short tons of "other sand" and 149,766 tons of gravel. Importations from other countries were very small.

[1] Figures on imports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

1950	9,191	25,481	290,025	266,065	146,079	29,011	445,295	320,557
1951	[4] 6,278	[4] 91,424	319,584	317,205	149,766	31,189	475,628	439,818

[1] Classification reads: "Sand containing 95 percent or more silica and not more than 0.6 percent oxide of iron and suitable for manufacture of glass."
[2] Classification reads: 1942–47: "Sand, n. s. p. f."; 1948–51: "Sand, n. s. p. f., crude or manufactured."
[3] Less than 0.5 ton.
[4] Includes 71 short tons valued at $80,847 from West Germany, believed to consist of a special type of silica not ordinarily included with glass sand.

TECHNOLOGY

Rejection of all minus-2-inch pit-run material in order to eliminate most of the objectionable constituents was a unique characteristic of a North Dakota sand-and-gravel operation.[2] This plant was producing coarse aggregate for Garrison Dam. The fine aggregate was being produced at another plant using a new type of hydraulic classifier known as the Super Sorter. At this operation coarse gravel was being reduced to fine sizes with rod mills.[3]

Recovery of sand and gravel from an extensive, although thin-bedded deposit, using both portable and stationary equipment was described.[4] Equipment and methods used abroad contrasted with those employed in the United States were covered in a description of a sand-and-gravel plant at Leeds, England.[5]

A large-scale operation handling up to 17,000 tons a day was described.[6] Flexibility and efficiency in meeting diverse specifications are attained by using a radial, belt-conveyor stockpiling system at one midwestern plant.[7]

Aggregate producers were doubtless interested in the large-scale use of fly ash as an additive in concrete used at Hungry Horse Dam in Montana. Such use was described in an article on various phases of aggregate production.[8] The economy and convenience of maintaining a central repair and spare parts unit to serve a multiple plant were discussed.[9]

A unique method of ocean-bottom dredging, pipeline conveyance, and wet placement of sand fill without subsequent compacting was described.[10] The high degree of efficiency that may be obtained in a portable sand and gravel plant was exemplified by a South Dakota operation.[11] The use of crushed olivine rock as foundry sand was a new development in regions like Washington, where silica sands are scarce.[12]

The National Sand and Gravel Association continued its fundamental research on aggregates and related subjects. Work conducted in 1951 included freezing and thawing cycles for accelerated weathering tests, air-entraining problems, and effects of additions of crusher screenings to sands. A method was devised for predicting the approximate 28-day strength of concrete from a known 7-day strength. Some of the accomplishments were outlined in Technical Information Letter 87, issued by the National Sand and Gravel Association, 1325 E Street NW., Washington, D. C., to member companies on December 19, 1951.

Secondary Metals—Nonferrous

By Archie J. McDermid[1]

GENERAL SUMMARY

THE SCARCITY of nonferrous metals which had become acute in 1950 continued throughout 1951. Secondary production was limited only by the availability of scrap for processing. Increased receipts of lead and aluminum scrap resulted in higher recovery of those metals for 1951 compared with 1950, whereas less copper and zinc scrap was available in 1951 than in 1950, and the secondary recovery of each was correspondingly lower. To provide adequate supplies of metal for military purposes and essential civilian needs, Government controls initiated in 1950 were increased in 1951. As scrap metals became scarcer prices rose higher, making ceiling price regulations necessary. Price ceilings for refined metal were generally established by the General Ceiling Price Regulation, which set maximum prices at the highest prices received by individual producers between December 19, 1950, and January 25, 1951, inclusive. The large number of scrap items of different compositions and the great variability of scrap prices made it difficult to determine and enforce

TABLE 1.—Salient statistics of nonferrous secondary metals recovered from scrap processed in continental United States, 1950–51

ceilings for scrap by means of the general regulation. Specific ceiling price regulations for most nonferrous scrap metals were therefore established during May and June. In addition to other measures used, the National Production Authority reinstituted the Controlled Materials Plan for copper, steel, and aluminum that had been in effect in World War II. Copper raw materials were placed under complete allocation, effective July 13, 1951.

TABLE 2.—Secondary metals recovered as unalloyed metal, in alloys, and in chemical compounds in the United States, 1947–51, in short tons

Metal	1947	1948	1949	1950	1951
Aluminum	344,837	286,777	180,762	243,666	**292,608**

[1] Revised figure.

Increased generation of aluminum process scrap, together with about the same quantity of old scrap as in 1950, provided aluminum-scrap consumers with enough raw material to increase their 1951 recovery of secondary aluminum 20 percent over that for 1950 in spite of the decline in activity in the second half of the year. The rise in secondary lead output for 1951 was due to increased consumption of used battery plates and drosses. Scarcity of scrap, following establishment of price ceilings, depressed operations in copper and zinc scrap enough to lower total secondary recovery for each below that in 1950.

SCOPE OF REPORT

Table 3 classifies the plants canvassed in nonferrous secondary metal surveys by type of operation and kind of material consumed. Plants have been recorded in more than one column if they used scrap items of more than one base; some smelters are listed as lead smelters, aluminum smelters, and copper smelters because they consumed lead-, aluminum-, and copper-base scrap. In the same way, some foundries have been counted as both aluminum and brass foundries. The tabulation of plants in some categories is subject to limitations. The large number of foundries and the small size of many of them make it impossible to obtain reports from all units. On the other hand, a few large corporations operating more than one plant prefer to file consolidated reports, in which the number and location of plants are not given. As a rule, response by the larger plants is excellent, so that coverage of quantities of metals consumed is better than coverage of plants.

The increase in primary aluminum plants from 32 in 1950 to 51 in 1951 results both from better coverage of and an increase in fabricating plants. There was also better coverage of aluminum foundries in 1951. The 131 secondary aluminum smelters include 56 alloy-ingot makers classed by NPA as limited smelters because their

TABLE 3.—Number and classification of plants in the United States consuming nonferrous scrap metals, refined copper, and copper-alloy ingots in 1951

Kind of plant	Type of materials used				
	Aluminum	Copper	Lead and tin	Zinc	All nonferrous types
Primary plants	[1] 51	[2] 16	8		
Secondary smelters	[3] 131	[4] 115	265	122	
Distillers				[5] 31	
Chemical plants	15	42		24	
Brass mills		65			
Wire mills		[6] 16			
Foundries and miscellaneous manufacturers	[7] 1,000		30	[8] 81	[9] 2,800

[1] Includes 12 aluminum-reduction plants and 39 rolling mills and extrusion plants which consumed aluminum scrap or ingot.
[2] Primary refineries and smelters which consumed copper-base scrap.
[3] Includes 128 aluminum-alloy ingot makers and 3 military aluminum smelters.
[4] Includes 78 secondary copper smelters and 37 smelters using copper scrap in other than copper alloys.
[5] Includes 20 secondary plants, 10 of which are zinc-dust plants, and 11 primary producers which used scrap in addition to ore.
[6] Refers to companies operating wire mills. Some companies operate more than 1 plant.
[7] Includes foundries using either aluminum scrap or ingot.
[8] Includes galvanizers, die casters and zinc rolling mills.
[9] Chiefly brass foundries, but some iron foundries, steel plants, and miscellaneous manufacturers. Any or all types of nonferrous scrap were used by these consumers. Figure shown is the number of plants on Bureau of Mines mailing list. Reports received estimated to account for about 91 percent of the total foundry output.

function was to melt scrap into ingot without analysis for shipment to smelters, classed as approved, for use in making specification alloy. The number of copper-chemical plants declined from 52 in 1950 to 42 in 1951 partly because some plants were unable to obtain copper materials for chemical manufacture. Some foundries expanded their operations to include brass ingot making, and some secondary copper smelters added brass-mill facilities to their establishments.

The reports from industry, on which data in this chapter are based, are received monthly from smelters, brass and aluminum rolling mills, wire mills, primary producers and some foundries and manufacturers. All the brass foundries, some manufacturers, and a number of the smaller aluminum foundries are canvassed on an annual basis.

Detailed information on primary metals may be found in the chapters devoted to those metals.

Definitions of terms used in this chapter follow:

Secondary metals are metals or alloys recovered from scrap and residues. The term "secondary" applies only to the source of the metal and has no relation to the type of product recovered, as to quality, degree of purity, or physical characteristics.

Scrap metals are divided into three main categories: Old scrap, process (or plant) scrap, and defective finished or semifinished articles returned by purchasers to be reworked.

Old scrap consists of metal articles that have been discarded because of wear, damage, or obsolescence, usually after serving a useful purpose. Typical examples of old scrap are discarded trolley wire, battery plates, railroad-car boxes, fired-cartridge cases, automobile crank cases, used pipe, plumbing fixtures from building demolition, lithographers' plates, and obsolete military equipment (frequently unused).

Digitized by Google

Process scrap or *plant scrap* is that generated during the manufacture of articles for ultimate consumption. Typical examples of process scrap are clippings, turnings, borings, skimmings, slags, and drosses. Process scrap is divided into two classifications: *Home scrap*, consumed in the plant of generation, and *new scrap*, which is consumed elsewhere, either after sale to another company or shipment to another plant of the same company.

Defective articles, the third main class of scrap, are classed as new scrap for tabulation purposes.

In this chapter consumption of old and new scrap only is tabulated, no record being kept, in nonferrous metal canvasses, of home scrap. Scrap generated in a machine shop and consumed in a foundry at the same plant location is considered home scrap, and its consumption is not tabulated. Consumption of scrap is always measured at the point where it loses its identity as scrap and becomes secondary metal. Consumption of scrap treated for a toll or conversion charge is reported by the plant at which the scrap is consumed, not by the plant owning the material.

Borings and turnings and other items of process scrap, when consumed outside the plant where generated, are new scrap, whether clean, rusty, or oily and whether generated recently or long before reclamation. Residues are new scrap if generated in processing scrap or refined metal. For example, flue dust from smelting brass scrap is new scrap. Zinc-chemical residues resulting from the consumption of zinc dust in the manufacture of sodium hydrosulfite are also new scrap. On the other hand, residues generated in processing ore or concentrates are not scrap but "primary residue." Old mine tailings are primary residue because generated in processing ore. Aircraft plants melt zinc-die alloys and antimonial lead to make dies and remelt the dies to make new ones whenever necessary. The same material may be remelted several times during a year. In such cases the dies are not considered to be scrap. If, however, they are sold to a smelter for redistillation or remelting they are considered to be old scrap.

Purchased scrap is a term used in nonferrous-scrap-metal questionnaires to cover all scrap that should be reported. It includes new scrap, old scrap, and toll scrap, all of which have passed through commercial transactions. It also includes scrap generated at one plant and transferred to another plant of the same company for processing, which usually involves transportation charges. The term also includes scrap reclaimed in shipyard repair work and from line operations at railroad foundries, although no definite financial transaction may have resulted.

SECONDARY ALUMINUM

The recovery of secondary aluminum from scrap totaled 292,608 short tons in 1951, a 20-percent increase over the 243,666 tons reclaimed from scrap processed in 1950. Prices of the various grades of scrap and secondary ingot fluctuated widely during the year. The value of aluminum recovered from scrap, computed on the basis of average prices received by primary producers for virgin pig, was $106,684,877. The average value of primary pig increased from 16.42

Digitized by Google

cents per pound in 1950 to 18.23 cents in 1951. The recoverable aluminum-alloy content of new nonferrous scrap consumed in 1951 increased 29 percent from 1950 to 216,017 short tons. Recovery from old scrap, however, remained about the same, totaling 76,591 tons compared with 76,358 tons in 1950.

TABLE 4.—Aluminum recovered from scrap processed in the United States, 1950–51, in short tons

Recoverable aluminum-alloy content of scrap processed			Aluminum recovered [1] from scrap processed		
Kind of scrap	1950	1951	Form of recovery	1950	1951
New scrap:					
Aluminum-base [2]	166,891	215,753	As metal	2,140	5,341
Copper-base	134	84	Aluminum alloys	239,577	283,938
Zinc-base	135	122	In brass and bronze	270	385
Magnesium-base	148	58	In zinc-base alloys	868	1,204
			In magnesium alloys	480	346
Total	167,308	216,017	In chemical compounds	331	1,394
			Grand total	243,666	292,608
Old scrap:					
Aluminum-base [3]	75,616	75,942			
Copper-base	104	129			
Zinc-base	429	238			
Magnesium-base	209	282			
Total	76,358	76,591			
Grand total	243,666	292,608			

[1] In accordance with common usage, the term "aluminum" covers aluminum alloys, and the figures include all constituents of the alloys recovered from aluminum-base scrap.
[2] Recoverable aluminum content of new aluminum-base scrap was 156,978 tons in 1950 and 201,563 tons in 1951.
[3] Recoverable aluminum content of old aluminum-base scrap was 70,981 tons in 1950 and 70,713 tons in 1951.

Despite a partial interruption of aluminum-scrap flow beginning in August, due to a price rollback ordered in June by the Office of Price Stabilization, consumption for 1951 increased to 332,296 tons compared with 273,192 tons in 1950. The increase was partly due to the previously mentioned increased coverage of foundries. Consumption of old scrap decreased, and the large increase in new scrap consumption was partly due to the increased usage of aluminum during 1950 and 1951. Apparent consumption of primary aluminum was 898,336 tons in 1950 and 975,244 in 1951 compared with 635,956 in 1949. A considerable part of the process scrap generated from the 1950 consumption was remelted in 1951, and it was expected that 1952 new-scrap consumption would reflect the high 1951 usage of primary aluminum.

Price ceilings for aluminum scrap and secondary ingot, established June 29, 1951, were below world prices, and scrap normally coming into the United States was diverted to foreign markets during the last half of the year. Competition for scrap between rolling mills and secondary smelters was keen throughout 1951. After establishment of price ceilings process scrap tended to return to the source of the ingot or sheet from which the scrap was generated. Production of primary ingot was so much greater than that of secondary ingot that if all process scrap was returned to the mill or smelter that supplied the raw material, secondary smelters would receive only a small percentage of the total. To correct the situation a section was added

to National Production Authority Order M–22, Distribution and Use of Aluminum Scrap, in an amendment effective December 17, 1951. The new section provided that NPA might issue specific directives to any person as to source, destination, consignee, or amount of scrap to be delivered or acquired by such person. The amendment, however, took effect too late to affect the flow of scrap in 1951.

The aluminum-alloy ingot produced by the secondary smelters is used chiefly by the foundries and die casters, and these plants also use some primary ingot and scrap as an auxiliary raw material. The independent secondary smelters consumed 70 percent, primary producers and independent fabricators 24 percent, and foundries and miscellaneous manufacturers 6 percent of the total aluminum-base scrap used in 1951; these percentages were virtually the same in 1950. The term "fabricators" includes aluminum rolling mills and extrusion plants, but not manufacturers of finished products.

Effective August 1, 1951, the Bureau of Mines report form for secondary aluminum smelters was changed to bring the classification of ingot up to date and to coincide as nearly as possible with the classification used by the industry. It is therefore necessary to show production for the first 7 months under the old and that for the last

TABLE 8.—Production of secondary aluminum and aluminum-alloy products in the United States, 1949–51, gross weight in short tons

Product	1949	1950	1951 [1]	
			January–July	August–December
Secondary aluminum ingot: [2]				
Pure aluminum (98.5 percent)	326	2,105	2,422	2,916
Silicon (Cu max., 1 percent)	7,376	10,393	10,930	
Aluminum-silicon (Cu max., 0.6 percent) alloys				5,048
Silicon (Cu, 1 to 2.5 percent)	3,532	5,395	3,678	
Aluminum-silicon (Cu, 0.6 to 2 percent) alloys				3,028
No. 12 alloy and variations	10,605	18,063	9,263	6,534

Aluminum powder [7]	17	35		
Aluminum-alloy castings	3,872	11,439	15,394	
Aluminum in chemicals	441	331	1,394	

[1] Classification of ingot for reporting to the Bureau of Mines was changed Aug. 1, 1951.
[2] Gross weight, including copper, silicon and other alloying elements at independent secondary smelters; total secondary aluminum and aluminum-alloy ingot contained 2,206 tons of primary aluminum in 1949; 5,339 tons in 1950; and 12,353 tons in 1951.
[3] Includes 1,785 tons produced at Naval Air Stations.
[4] Of the totals, 1,810 tons was produced in 1950; 641 tons in January–July, 1951; and 797 tons in August–December 1951, at Naval Air Stations and United States Air Force Bases.
[5] Negative production indicates consumption of this material at smelters greater than production.
[6] Includes aluminum rolling mills and extrusion plants, but not manufacturers of final products.
[7] Does not include production measured as ingot for graining, powder, atomizing, or chemical purposes.

Digitized by Google

5 months under the new classification. Total production of secondary aluminum-base ingot as reported to the Bureau of Mines was 201,669 short tons (an increase of 13 percent) compared with 179,247 tons produced in 1950. Shipments of aluminum castings were 275,217 short tons, according to data published by the Bureau of the Census. Assuming that production equaled shipments and that all of the 201,669 tons of secondary ingot produced was consumed in making castings, the other seventy-odd-thousand tons of castings was made from scrap and from ingot supplied by primary producers.

Imports of aluminum scrap, most of which were actually in pig form, in 1951 were 20,009 tons compared with 67,959 tons in 1950. Exports were 1,460 tons in 1951 and 800 tons in 1950.

The monthly average price paid by dealers for cast-aluminum scrap was 15.75 cents a pound in January and 17.25 cents in May and June but dropped to 7.75 cents in July and remained there for the rest of 1951. Ceiling prices for aluminum scrap and secondary aluminum ingot were established on June 29, 1951. The monthly average price for new aluminum clippings was 19.25 cents in January, reached 21.75 cents in May and June, and averaged 10.50 cents for the remainder of 1951.

The monthly average price of secondary aluminum ingot (No. 12 alloy, at New York, as quoted by the American Metal Market) was 30.14 cents a pound in January, rose to 31.12 in April and May, was 30.57 cents in June, and was quoted at 19.50 cents for the remaining months of the year, following establishment of secondary aluminum ingot ceiling prices. The price of primary aluminum pig (New York, American Metal Market) was 19 cents a pound throughout the year.

SECONDARY ANTIMONY

Recovery of secondary antimony in 1951 from lead- and tin-base scrap totaled 23,943 short tons valued at $21,151,246, an increase of 10 percent in quantity and 64 percent in value over the 21,862 tons valued at $12,859,228 recovered in 1950. The values are computed at 29.41 cents per pound for 1950 and 44.17 cents for 1951, the average New York selling price in each year.

Secondary copper and lead smelters recovered 20,446 tons (85 percent of the total), primary lead smelters 2,060 tons (9 percent), and manufacturers 1,437 tons (6 percent).

Consumption of battery plates increased 19 percent over 1950 and yielded 55 percent of all antimony reclaimed. Antimony reclaimed in antimonial lead increased 26 percent, but recovery declined in other lead alloys and in tin-base alloys.

Data on consumption of scrap from which antimony was recovered may be found in the tables on consumption of lead- and tin-base scrap in the Lead-Scrap Consumers Reports published monthly by the Bureau of Mines. Products in which antimony was recovered are included in the lead- and tin-products table in the secondary lead section of this chapter. So far as known, all secondary antimony was reclaimed in lead and tin alloys, none being recovered as unalloyed metal.

TABLE 9.—Antimony recovered from scrap processed in the United States, 1950–51, in short tons

Recoverable antimony content of scrap processed			Antimony recovered from scrap processed		
Kind of scrap	1950	1951	Form of recovery	1950	1951
New scrap:			In antimonial lead	13,326	16,747
Lead-base	3,091	4,006	In other lead alloys	8,299	7,033
Tin-base		1	In tin-base alloys	237	163
Total	3,091	4,007	Grand total	21,862	23,943
Old scrap:					
Lead-base	18,602	19,768			
Tin-base	169	168			
Total	18,771	19,936			
Grand total	21,862	23,943			

The price of domestic antimony for carlots, New York, equivalent of the f. o. b. Laredo base, averaged 37.24 cents a pound in January 1951, increased to 43.78 cents in February, remained near that price through October, and increased to 46.63 cents in November and to 51.85 cents in December, the average for the year being 44.17 cents.

SECONDARY COPPER AND BRASS

Recovery of copper from all classes of nonferrous scrap totaled 932,282 short tons valued at $451,224,488 in 1951, a 5-percent decrease in quantity and an 11-percent increase in value from the 977,239 tons valued at $406,531,424 recovered in 1950. These values are computed at the average weighted price for all grades of refined copper sold by producers in the 2 years, that is, 20.8 cents per pound in 1950 and 24.2 cents in 1951.

TABLE 10.—Copper recovered from scrap processed in the United States, 1950–51, in short tons

Recoverable copper content of scrap processed			Copper recovered from scrap processed		
Kind of scrap	1950	1951	Form of recovery	1950	1951
New scrap:			As unalloyed copper:		
Copper-base	485,054	464,226	At primary plants	189,746	135,023
Aluminum-base	6,765	9,595	At other plants	70,958	51,439

The decline was due chiefly to lowered scrap operations of the primary copper producers, who recovered 144,000 tons of secondary copper in 1951 and 195,000 in 1950. Secondary smelters and brass mills reclaimed 325,000 and 315,000 tons of copper respectively in 1951, which in each case was not far below the figure for 1950. Foundries reported recovery of 123,000 tons of copper from scrap in 1951, 6,000 more than in 1950, but the increase probably reflected better coverage of foundries by the 1951 canvass rather than actual greater recovery. Reporting on consumption of copper materials was made mandatory in 1951 after having been on a voluntary basis previously, except for the World War II period. The mandatory feature of the reports and the greater willingness of respondents to report were largely responsible for the increased coverage of all consumers in 1951, although all the primary producers reported in both 1950 and 1951. The total published recovery of copper by brass mills and secondary smelters in 1950 included estimated tonnages for those that did not report, but no such estimate was made for foundries.

The decreased consumption of copper-base scrap and the resultant lower secondary production by primary producers in 1950 were ascribed to the relationship between prices for virgin metals and scrap. Theoretically, establishment of ceiling prices for scrap, which

took place in the middle of 1951, should have allowed each group of consumers to obtain the same proportion of the available scrap as in the period before restrictions of any kind were imposed. However, the competitive position of the primary producers, which should have been improved, deteriorated, as indicated in the previous paragraph. The scarcity of scrap is also indicated in the inventory figures. Stocks of copper-base scrap held by primary producers were 57 percent less at the end of 1951 than at the beginning, those of the secondary smelters 36 percent less, those of the foundries 30 percent less, and those of the brass mills 6 percent less. Monthly inventories fell below monthly consumption in the latter part of 1949. In the latter half of 1950 and during 1951, stocks on hand were considerably less than an average month's consumption, or 30 days' supply.

One reason for the scrap shortage was the decline in imports of copper and brass scrap to 13,315 tons in 1951 from 71,779 tons in 1950. In the absence of statistics on the generation of scrap, it was not clear whether lower generation or withholding of scrap by speculators, Government agencies, generators, or others, or both of these conditions were also causes of the short supply. Consumers' stocks and receipts of scrap are known, but in the absence of data on generation, stocks held by others than consumers cannot be determined.

In 1951, as in 1950, slightly over half of the total secondary copper recovery was from new scrap. Recovery increased in 1951 in all forms except unalloyed copper and in the minor item of alloys other

[1] Revised.
[2] Of the totals shown, chemical plants reported the following: Unalloyed copper scrap, 1,273 tons of new and 10,815 tons of old; copper-base alloy scrap, no new and 470 tons of old.

than copper, aluminum, and iron. Total copper recovered from old copper-base scrap decreased somewhat in 1951, but that recovered by brass mills increased over 20,000 tons or more than 100 percent because of increased consumption of fired cartridge cases. Brass mills use chiefly process scrap but can treat fired cartridge cases without difficulty if they have been detonated and are free from steel shells. Cartridge-case scrap was channeled to brass mills in 1951 by the National Production Authority because that scrap is most economically used in making cartridge brass, a brass-mill product.

Use of unalloyed copper scrap by all groups declined in 1951, but operations of the secondary smelters were affected less than those of other groups. This scrap is sought by all groups, by the primary producers because it is easily refined, and by the others for use in place of refined copper as an alloying ingredient. Nearly all the worn-out railroad-car boxes consumed as scrap were used by the railroad foundries and bearing companies (62,236 tons in 1950 and 71,761 in 1951), which remelt them to make new bearings. The smelters find difficulty in using them for alloying purposes because the antimony in the bearing metal is difficult to remove entirely and is regarded as an impurity in copper-base alloys. Brass mills consumed most of the nickel-silver scrap, which, for tabulation purposes, includes cupronickel. The latter is used to make the best grade of condenser tubes for use especially in warships. A total of 221,549 tons of refinery brass, low-grade scrap, and residues was used in 1951 compared with 319,234 tons in 1950. The primary producers consumed 71 percent of the total in 1951 and 85 percent in 1950, with the secondary smelters using nearly all of the remainder. The primary producers generally smelt their raw material, both scrap and primary, in blast furnaces or reverberatories to make a matte, which is then changed in a converter to blister copper. This equipment is better suited to the use of slags, irony brass, and other low-grade residues than the reverberatories and melting furnaces employed

[1] Gross weight of brass and bronze ingot. Includes 276,646 tons of copper, 11,726 tons of lead, 659 tons of nickel, 10,321 tons of tin, 37,266 tons of zinc, 103 tons of aluminum, and 3,966 tons of primary metals in 1950; and 285,480 tons of copper, 12,159 tons of lead, 575 tons of nickel, 10,202 tons of tin, 38,655 tons of zinc, 121 tons of aluminum, and 18,562 tons of primary metal in 1951.

[2] Gross weight of secondary brass and bronze in commercial shapes. Includes 298,900 tons of copper, 2,904 tons of nickel, 4,646 tons of lead, 467 tons of tin, 111,499 tons of zinc, and 125 tons of aluminum in 1950; and 298,014 tons of copper, 2,340 tons of nickel, 5,060 tons of lead, 415 tons of tin, 118,203 tons of zinc, and 45 tons of aluminum in 1951.

[3] Gross weight of secondary metal in brass and bronze castings. Includes 104,709 tons of copper, 74 tons of nickel, 13,735 tons of lead, 5,591 tons of tin, 7,812 tons of zinc, and 42 tons of aluminum in 1950; and 108,617 tons of copper, 15,146 tons of lead, 5,525 tons of tin, 8,545 tons of zinc, 47 tons of aluminum, and 15 tons of nickel in 1951.

by most of the secondary smelters. A few of the larger secondary smelters and foundries, however, used blast furnaces or cupolas in 1951.

The largest increase in production of brass ingot in 1951 was 7,169 tons of manganese bronze, the best grades of which are made from refined metal only. It is used for propellers and other castings in which high corrosion resistance is needed.

Table 17, Consumption of Copper Materials by Principal Consuming Group, should be considered with table 3, in the General Summary section of this chapter, which gives number and classification of consuming plants. Although about 2,800 brass foundries, including a few miscellaneous manufacturers, are listed as respondents, those reporting totaled 2,300. Of these, 845 reported consumption of copper-base scrap, 1,465 consumption of copper-alloy ingot, and 273 use of nonferrous scrap other than copper-base. It will be seen that the material consumed by the primary producers, which includes

[2] Detailed information on consumption of refined copper is given in the Copper chapter of this volume.
[3] Excludes chemical plants.

imported blister copper refined in this country, is approximately adequate to provide the refined copper shown as consumed by the other groups. The brass ingot shown as consumed by the brass mills, wire mills, and foundries represents the output of the secondary copper smelters, except for about 35,000 tons of refined copper and chemicals in 1951 and 50,000 in 1950.

Consumption of brass ingot actually reported by foundries responding to Bureau of Mines questionnaires was 19 percent greater in 1951 than in 1950, totaling 325,786 short tons compared with 273,433 tons. In addition to the 325,786 tons reported by the foundries, 8,657 tons was consumed by brass and wire mills, and 2,077 tons was exported. Data on imports of brass ingot are not available. Brass-ingot makers shipped 370,267 tons of brass ingot to foundries in 1951 and 343,959 tons in 1950. On the assumption that shipments equal domestic consumption plus exports, the foundry-consumption survey achieved 91 percent coverage in 1951 compared with 80 percent in 1950. Over 3,000 plants were canvassed both years.

In table 18 the ingot consumption reported in the 1951 foundry survey has been classified by nine general types, and by States and geographic divisions. Similar breakdowns for earlier years have been published in past Minerals Yearbooks.

The 1951 increases in consumption were more apparent than real. Reporting on consumption of brass ingot and other copper materials was made mandatory in 1951, after having been on a voluntary basis for the period between World War II and the Korean conflict. The mandatory feature of the reports and the greater willingness of respondents to report increased the number of reports received and the reported consumption. Actual consumption of ingot by the foundries in 1951 probably increased about 8 percent, or the same as the increase in shipments of ingot by ingot makers.

Dealers' buying prices for No. 1 composition scrap increased from an average of 17.25 cents a pound in January to 22.50 cents in May, then declined to an average of 18.42 cents in August. From Sep-

tember to the end of 1951, inclusive, 18.25 cents was the average paid. The price of No. 1 heavy copper scrap averaged 20 cents a pound in January, increased each month reaching 26 cents in May, then declined to 19 cents in August, remaining at that level for the remainder of 1951. Ceiling prices for copper-base scrap were established on June 26 but did not become fully effective for several weeks. They applied to consumers, but dealers were not required to abide by ceiling prices for scrap metals in 1951.

NPA Order M–16, which became effective December 18, 1950, contained rules to insure the continuous flow of copper-base scrap into normal channels of distribution. As amended, effective July 13, 1951, it was expanded to control acceptance and delivery of all copper raw materials including refined copper, copper-base alloys and intermediate shapes, as well as copper-base scrap.

TABLE 19.—Brass and copper scrap imported into and exported from the United States, 1947–51, in short tons

	1947	1948	1949	1950	1951
Imports for consumption:					
Brass scrap	112,393	59,984	23,486	[1] 37,537	6,523

Exports:					
Brass scrap	3,157	6,584	13,963	[1] 9,054	4,857
Scrap copper	969	2,266	8,284	9,445	7,701

[1] Revised figure.

SECONDARY LEAD

The quantity of secondary lead recovered increased 7 percent in 1951 to 518,110 tons, valued at $179,266,060, compared with 482,275 tons, valued at $130,214,250, in 1950. Approximately the same coverage of the industry was obtained in the survey for both years, and greater demand for lead was responsible for the increased recovery rather than additional reporting companies. The value of lead recovered has been computed for both years on the basis of the yearly average weighted prices of all grades of refined lead sold by producers, or 13.5 cents a pound in 1950 and 17.3 cents in 1951. For the sixth consecutive year, recovery of lead from scrap was greater than domestic mine production.

Shipment of secondary lead as metal increased from 135,178 tons with a secondary lead content of 129,313 tons in 1950 to 171,907 tons with a secondary content of 168,916 tons in 1951—a gain of 31 percent in lead content. Secondary antimonial lead products shipped totaled 261,157 tons with a secondary lead content of 229,963 tons—a slight increase over 1950—but lead recovered in solder, type metals, and lead babbitt declined 13, 14, and 1 percent, respectively. Total output of the secondary lead industry, including the primary metals added to scrap, was 6 percent greater than in 1950. Primary metals so used, however, dropped from an average of about 12,000 tons a month in 1950 to 8,500 tons in 1951. Secondary smelters consumed 103,668 tons of primary metal during the year, of which 74,465 tons was soft lead, 8,288 tons antimonial lead, 14,447 tons primary and detinners' brand tin, 6,108 tons primary antimony in metal and in ore, and 360 tons miscellaneous metals, such as arsenic and bismuth.

[1] Most of the figures herein represent shipments rather than production of the items involved. However, it has been necessary to record actual production figures in some instances where the information is procured from reports on that basis.

[2] Difference between gross weight of products and secondary metal content represents added primary metals or impurity content.

Primary lead refiners reclaimed 38,196 tons of lead from scrap in 1951 or 7 percent of the total. Of this quantity, 3,893 tons was refined soft lead and 34,303 in antimonial lead; antimony content of the antimonial lead was 2,060 tons.

Smelters and foundries consumed 673,780 tons of lead-base scrap during 1951—an increase of 10 percent over 1950. The increase was due almost entirely to a 19-percent gain in battery plates treated and a

Digitized by Google

49–percent gain in the use of drosses and residues. Consumption of soft lead scrap declined 4 percent, antimonial lead 45 percent, cable lead 37 percent, and solder 34 percent. Smelter operations were highest in the first and last quarters of 1951 and reached the lowest point in September.

TABLE 22.—Stocks and consumption of new and old lead scrap at smelters and refiners in the United States in 1951, gross weight in short tons

Scrap item	Stocks, beginning of year [1]	Receipts	Consumption			Stocks, end of year
			New scrap	Old scrap	Total	
Soft lead	2,943	58,367	----------	58,208	58,208	3,102

Total	60,884	648,673	99,230	555,565	654,795	54,762

[1] Revised.

Owing to the expanding national-defense program and a decline in the available supply, lead was brought under inventory control on February 16 through the National Production Authority Order M–38. On June 29 the Office of Price Stabilization issued Ceiling Price Regulation 53 rolling back prices on scrap and secondary lead to 15.25 and 17.00 cents per pound, respectively, and established a ceiling on battery-plate smelting at $40 a ton. The move was deemed necessary to correct the "abnormal price relationship" between primary and secondary metal. The 17-cent ceiling price for primary lead had been effective since January 26, but uncontrolled secondary lead and even scrap lead were often selling well above the ceiling price for primary metal. According to the Statement of Considerations in CPR 53, some sellers were obtaining 21 cents a pound or more for secondary lead during the December 1950–January 1951 general price-freeze period compared with the primary lead price of 17 cents a pound. Ordinarily high-grade secondary refined lead sells at about the same price as primary lead. On October 2 a ceiling of 19.00 cents was authorized for primary lead, but the corresponding adjustment for scrap and secondary lead was not made until October 22. No further price change occurred during the remainder of 1951. Keen competition for battery plates during the first two-thirds of 1951 kept the smelting charge well below the $40 limit. In January the most quoted charge was from $30 to $35, decreasing to $20 by March 31 and then dropping by June 22 to "nil to $5." By the middle of August the rate had again advanced to the $40 ceiling, where it remained through December 31.

Percentage and remelt metals circulated inside the secondary lead industry totaled 33,365 tons in 1951, consisting of 4,168 tons of solder, 3,981 of lead babbitt, 7,657 of soft lead, 15,341 of antimonial lead, 1,509 of type metals, 288 of cable lead, 377 of tin babbitt, 38 of remelt tin, and 6 of pewter. In addition, smelters shipped to consumers

[1] Revised.

467,005 tons of these metals during the year and held in inventory 27,548 tons on December 31.

General imports of lead scrap totaled 9,082 short tons (lead content) in 1951 compared with 20,085 tons (lead content) in 1950.

SECONDARY MAGNESIUM

Secondary magnesium recovered from scrap in 1951 totaled 11,526 short tons (valued at $5,647,740) compared with 9,476 (revised) tons (valued at $4,175,125) in 1950. Values have been calculated at 22.03 cents a pound for 1950 and 24.5 cents for 1951, the average prices for magnesium ingot (98.5 percent), f. o. b. Freeport, Tex., for the 2 years. Primary production in 1951 was 40,881 tons. Of this a little over half was produced at the Dow Chemical Co. Freeport, Tex. plant, and the remainder at six Government-owned plants which were reactivated during the year.

Magnesium-scrap consumption increased from 8,367 tons in 1950 to 10,388 tons in 1951 (24 percent). Consumption of primary magnesium and the magnesium content of primary alloy rose from 18,051 tons in 1950 to 35,710 in 1951 (98 percent). It would seem that the increased use of primary material in 1951 would have been reflected in increased consumption of process scrap to a greater degree than reported. However, most Government-owned plants did not attain full production until late in 1951, so that most of the scrap generated by fabricators in processing ingot received from the Government-owned plants and processed for defense in 1951 did not return to remelters before 1952. Two-thirds of the total scrap used in both 1950 and 1951 was consumed by five large companies, all of which operated smelters and some of which operated foundries and fabricating plants as well.

Small foundries can use their magnesium home scrap, but it is not practicable for them to use purchased scrap unless they know the composition because, unlike brass scrap, its composition cannot be identified by its color but must be determined by laboratory analysis. It is more economical for such plants to buy ingot of specified composition than to mix and analyze their own alloys.

Foundries used about 3,000 tons of primary unalloyed magnesium ingot, 10,000 of primary magnesium alloy ingot, 4,000 of secondary magnesium ingot, and 2,000 of magnesium scrap in magnesium castings in 1951. In comparison, brass foundries used about 39,000 tons of refined copper, 355,000 of brass ingot and 161,000 of scrap. Scrap constituted 11 percent of the raw material used in magnesium castings and 29 percent of the raw material used in brass and bronze castings.

TABLE 25.—Stocks and consumption of magnesium scrap in the United States in 1951, gross weight in short tons

Scrap item	Stocks, beginning of year	Receipts	Consumption			Stocks, end of year
			New scrap	Old scrap	Total	
Cast scrap	[1] 2,308	6,094	682	6,139	6,821	1,581

Borings, grindings, drosses, etc.	[1] 41	755	657	.....	657	139
Total	[1] 2,505	9,712	4,249	6,139	10,388	1,829

[1] Revised figure.

Of the 11,526 tons of secondary magnesium recovered in 1951, 5,662 tons (49 percent) was reclaimed by melting scrap to make magnesium-alloy ingot, some of which was classed as primary ingot because more primary material than scrap was used in making it. Consumption of secondary magnesium ingot totaled 5,059 tons, including, in addition to 3,888 tons used in castings, 1,074 in aluminum alloys and 97 in cathodic protection. The figures for magnesium recovered from aluminum scrap show large increases because Bureau of Mines magnesium percentages of several types of aluminum scrap were revised upward to allow for increased use of magnesium in aluminum alloys.

Although magnesium was on the critical list of defense materials, mandatory Government control was not exercised in 1951. The

Digitized by Google

National Production Authority directed distribution of all primary magnesium produced at the Government-owned plants for defense. By cooperative agreement the Dow Chemical Co., the only private producer of the primary metal, gave first priority to delivery of magnesium on defense orders.

The price of primary magnesium remained at 24.5 cents a pound throughout the year, whereas remelt magnesium ingot was quoted at 32 cents. These prices were in effect during the base period at the end of 1950 for determining maximum prices under the General Ceiling Price Regulation.

SECONDARY NICKEL

The recovery of secondary nickel from nonferrous scrap in 1951 totaled 8,602 short tons, valued at $9,759,829, a decrease of 2 percent in quantity from the 8,795 tons, valued at $8,408,020, recovered in 1950. The values have been calculated at 56.73 cents a pound for 1951 and 47.80 cents for 1950, the average spot-delivery prices of Grade F nickel ingots and shot in 10,000-pound lots at New York.

TABLE 26.—Nickel recovered from scrap processed in the United States, 1950–51, in short tons

Recoverable nickel content of scrap processed			Nickel recovered from scrap processed		
Kind of scrap	1950	1951	Form of recovery	1950	1951
New scrap:			As metal	535	684

Lead-base		2			
Total	4,781	4,814			
Grand total	8,795	8,602			

[1] Includes only nonferrous nickel scrap added to cast iron and steel.

As in 1950, more secondary nickel was recovered in copper-base alloys in 1951 than in any other way, but the percentage of the total so recovered decreased from 40 in 1950 to 30 in 1951. Nickel recovered from nonferrous scrap in iron and steel, which had risen from 1,201 tons in 1949 to 1,824 tons in 1950, increased to 2,149 tons in 1951. Nickel recovered in nickel-base alloys declined 18 percent in 1951 to 1,096 tons, or to about the same quantity as in 1949.

In addition to 14,914 tons of nickel-silver scrap, a copper-base item, 7,164 tons of nickel-base scrap were consumed in 1951. The corresponding figures for 1950 were 21,060 and 6,441 tons, respectively. The recoverable nickel content of the 14,914 tons consumed in 1951 was calculated to be 2,438 tons, and this was the total recovery of nickel from old and new copper-base scrap as shown in the recovery table. This is close to the quantity of nickel reported as recovered

[2] Copper-base scrap, and so tabulated except in this table and table 28.

in copper-base alloys, as shown in the same table. These proportions obtained for previous years as well, indicating that all or nearly all the nickel-silver scrap and little if any nickel-base scrap were used in copper-base alloys. The nickel silver shown as consumed in the manufacturers and foundries scrap table was used chiefly by brass mills. The increased reported consumption of nickel residues as indicated in this table was due to better coverage of plants reclaiming nickel from spent nickel catalyst.

TABLE 28.—Stocks and consumption of new and old nickel scrap at foundries and plants of other manufacturers in the United States in 1951, gross weight in short tons

[1] Revised.
[2] Copper-base scrap, and so tabulated except in this table and table 27.

Distribution and use of nickel and use of nickel scrap were controlled during the first 7½ months of 1951 by means of National Production Authority Order M–14. In M–80, which replaced M–14 on August 15, the provisions of the latter order were continued, and control was expanded. The use of nickel and nickel scrap for nickel-plating many products was prohibited, and the primary metal was placed under complete allocation. In Ceiling Price Regulation 29, issued May 3, 1951, maximum prices for nickel scrap, including nickel-bearing steel scrap, were established.

During the first 4 months of 1951, while the price of primary nickel was 53.80 cents a pound, prices quoted by dealers at New York were 45 cents a pound for nickel clippings and 33 cents for monel clippings. On May 8 ceiling prices for nickel scrap were established, including

Digitized by Google

40.5 cents for nickel clippings and 33 cents for monel clippings; these prices were in force for the remainder of 1951. On June 2 the price of primary nickel was raised to 58.83 cents, but ceiling prices for nickel scrap were not changed.

Imports of nickel scrap in 1949, 1950, and 1951 were 1,429 tons, 625, and 791, respectively. Exports in 1951 totaled 3,992 tons, compared with 2,838 in 1950.

SECONDARY TIN

Secondary tin recovered in 1951 totaled 34,434 tons, valued at $88,363,153, a 3-percent decrease in quantity from the 35,481 tons, valued at $67,809,158, reclaimed in 1950. Values are computed at 95.557 cents for 1950 and 128.308 cents for 1951, the average New York selling price of Straits tin in each year.

At detinner plants and secondary smelters and in the forms of metal and in alloys (with the exception of copper-base alloys), secondary tin recovered was less than in 1950. Detinners produced 3,529 tons of pig tin from old tin cans and new tin-plate clippings, and secondary smelters reclaimed an additional 166 tons. The total tin reclaimed as metal (3,695 tons) was 9 percent under that recovered as metal in 1950. Recovery in solder, babbitts, chemical compounds, and lead-base alloys all declined considerably, but recovery of tin in brass and bronze increased 30 percent. Shipments of secondary tin and lead-tin alloys are presented in the section on Secondary Lead in this chapter.

Secondary smelters and foundries consumed 6,211 tons of tin-base scrap, an increase of 12 percent over the quantity of scrap treated in 1950. However, the greatest increase was in residues treated, which yield a comparatively low quantity of metal and did not therefore raise total recovery proportionately.

TABLE 29.—Tin recovered from scrap processed in the United States, 1950–51, in short tons

Late in 1950 inventory control of alloys and other materials containing tin had been effected and limits set on nondefense uses, by means of National Production Authority Order M–8, the order applying to scrap and secondary tin as well as primary. On January 9, 1951, the order was amended permitting smelters and refiners of secondary tin maximum use of tin scrap in the production of pig tin, alloys, and chemicals. The amendment was designed to encourage conversion of tin-bearing scrap to usable metal. Another amendment to M–8 on January 27 further restricted the end use of tin (including secondary tin); on March 2 the metal was placed under complete allocation.

The average monthly price of scrap tin pipe was 90 cents a pound in January, rose to $1.19 in February, and gradually declined thereafter to 90 cents in December, following the trend of prices for primary metal.

Exports of tin-base scrap totaled 6,182 short tons in 1951, almost double the quantity exported in 1950, and consisted mostly of drosses and residues.

Secondary tin recovered by detinning plants, as metal and in chemical compounds, decreased 9 percent in 1951 compared with 1950. The total tin recovered was 4,071 short tons in 1951 against 4,467 in 1950. Tin-plate clippings and old cans were the source of 3,992 tons in 1951, of which 3,529 were reclaimed as metal in the form of pigs, and 463 tons in the form of tin compounds. During 1950 the usage of such material provided 4,341 tons, comprising 3,697 tons of metal

Tin recovered:		
From new tin-plate clippings, short tons	4,221	3,826
From old tin-coated containers, do	120	166
Total, do	4,341	3,992
Form of recovery:		
As metal, do	[1] 3,697	[1] 3,529
In compounds, do	644	463
Total, do	[2] 4,341	[2] 3,992
Weight of tin compounds produced, do	1,375	958
Average quantity of tin recovered per long ton of clean tin-plate scrap used, pounds	17.98	15.89
Average quantity of tin recovered per long ton of old tin-coated containers used, pounds	14.30	14.98
Average delivered cost of clean tin-plate scrap, per long ton	$30.00	$41.28
Average delivered cost of old tin-coated containers, do	$20.97	$32.45

[1] Includes a small tonnage of pig tin of less than standard purity and consequently subject to further refining or alloying.

[2] Recovery from tin-plate clippings and old containers only. In addition, detinners recovered 69 tons of tin as metal and 57 tons of tin in compounds from tin-base scrap and residues in 1950 and 79 tons of tin in compounds from these sources in 1951.

and 644 in compounds. The treatment of other tin-bearing materials accounts for the remaining production of 79 tons in 1951 and 126 in 1950.

The industry reported treating 481,443 long tons of tin-plate clippings in 1951. This was the largest tonnage of record and exceeded the previous peak reached in 1950 by nearly 3 percent. The average cost of such clippings delivered at plants increased from $30 a long ton in 1950 to $41.28 in 1951. Steel scrap is one of the products of the detinning industry, being sold to open-hearth mills. The average quoted composite price of No. 1 Heavy-Melting steel scrap was $43.15 in 1951—the highest on record. Ceiling prices for steel scrap were established by the Office of Price Stabilization, effective February 7, 1951. Old cans processed increased 32 percent to 22,131 long tons in 1951, compared with 16,818 tons in 1950; this was a small tonnage, however, in comparison with the record use of 175,870 tons in 1943. Tin recovered from tin-plate clippings in 1951 was 3,826 tons, 9 percent less than 1950, while that from old cans, 166 tons (mostly in the form of pig tin), increased 38 percent.

The average quantity of tin recovered per long ton of tin-plate scrap treated was 15.89 pounds in 1951 compared with 17.98 pounds in 1950. Before the introduction of electrolytic tin plate and wartime restrictions on the weight of tin on the hot-dipped product recoveries averaged about 37 pounds per ton of material detinned. Lower recoveries have for several years continued to reflect the treatment of a larger proportion of electrolytic tin plate carrying a much thinner coating of tin than the hot-dipped product. The average quantity of tin recovered per long ton of old tin-coated containers increased slightly from 14.30 pounds in 1950 to 14.98 pounds in 1951.

TABLE 33.—Tin-plate scrap imported into the United States, 1950–51, by countries, in long tons

[U. S. Department of Commerce.]

Country	1950	1951
Australia	8,094	11,169
Canada	21,690	23,364
Cuba	1,302	2,039
French Morocco	3,321	2,716
New Zealand	156	2,028
Sweden	528	2,323
Union of South Africa	5,247	6,187
All others	2,056	1,745
Total	42,394	51,571

Imports of tin-plate scrap were 51,571 long tons in 1951 against 42,394 in 1950 (detinned, this material would yield about 400 tons of tin). In 1951 exports of tin-plate scrap were 810 long tons (562 in 1950), mostly to Mexico and Japan.

SECONDARY ZINC

Secondary zinc recovered in 1951 from purchased scrap and residues totaled 314,377 short tons, with a value of $114,433,228, representing a decrease in quantity of 4 percent from the 326,030 tons, valued at $92,592,520, recovered in 1950. In comparison, mine production of recoverable zinc in the United States was 681,189 tons, valued at $247,952,796 in 1951, and 623,375 tons, valued at $177,038,500 in 1950. The values have been calculated at the average weighted price for all grades of refined zinc sold by producers, which was 14.2 cents in 1950 and 18.2 cents in 1951.

TABLE 34.—Zinc recovered from scrap processed in the United States, 1950–51, in short tons

Digitized by Google

Recovery of zinc from zinc-base scrap decreased to 147,919 tons in 1951 from 167,012 in 1950, whereas recovery of zinc from copper-base scrap increased 5 percent, or to 165,403 tons. This increase was caused chiefly by the brass mills, which used only about 1,500 tons more of copper-base scrap in 1951 than in 1950, but the zinc content of the scrap used was 5,000 tons greater in 1951. The lowered recovery of zinc from zinc scrap may be attributed in part to the general nonferrous scrap shortage and to the decreased use of slab zinc in galvanizing to 400,000 tons in 1951 from 442,000 in 1950. All the dross (the principal zinc-scrap item), all the sal skimmings, and a large part of the dry skimmings generated come from galvanizing operations.

TABLE 35.—Production of secondary zinc and zinc-alloy products in the United States, 1947–51, gross weight in short tons

Products	1947	1948	1949	1950	1951

[1] Revised.

Foundries do not consume much zinc scrap; most of the scrap, including all of the residues, as reported in the table for stocks and consumption of scrap by chemical plants, foundries, and other manufacturers was consumed by chemical plants. A few zinc-distillation plants have chemical departments. In such cases consumption of residues is credited to distillers. Some skimmings were roasted by smelters before being used by the chemical plants. The dry skimmings consist of zinc oxide and metallic zinc and are roasted to convert the metallic zinc to oxide which is more easily dissolved. If sal ammoniac

Digitized by Google

or zinc ammonium chloride flux is used in galvanizing, the dry skimmings will contain some chlorine; that is, they will be contaminated to some extent with sal skimmings, which contain zinc oxychloride as explained in the zinc section of the Secondary Metals chapter in the 1950 Minerals Yearbook. The chlorine is vaporized as zinc chloride in the roasting operation and is lost in the exhaust gases. Sal skimmings can, however, be used by the chemical plants in making zinc chloride without previous roasting. The price paid for sal skimmings to be shipped to the Philadelphia area in 1951 was $30 to $35 a ton f. o. b. shipping point.

TABLE 37.—Stocks and consumption of new and old zinc scrap at chemical plants, foundries and other manufacturers in the United States in 1951, gross weight in short tons

Scrap item	Stocks, beginning of year [1]	Receipts	Consumption			Stocks, end of year
			New scrap	Old scrap	Total	
Clippings	185	4,235	4,345	----	4,345	75
Sheet and strip	23	347	----	357	357	13
Engravers' plates	4	214	----	212	212	6
Skimmings and ashes	610	12,160	12,442	----	12,442	328
Sal skimmings	3,794	24,084	26,640	----	26,640	1,238
Die-cast skimmings	----	3	3	----	3	----
Die castings	24	1,623	1,263	356	1,619	28
Flue dust	650	3,926	4,015	----	4,015	561
Chemical residues	1,222	14,056	13,714	----	13,714	1,564
Total	6,512	60,648	62,422	925	63,347	3,813

[1] Revised.

Total consumption of zinc byproduct residues, excepting dross but including skimmings, flue dust, and chemical residues, increased to 127,000 tons in 1951 from 126,000 tons in 1950, but recovery of secondary zinc in chemicals declined 3,000 tons. However, some of the residues in each year were distilled with primary zinc concentrates to produce slab zinc. One plant reported production of redistilled slab zinc from skimmings which were not mixed with concentrates.

Of the zinc scrap consumed in 1951, only 11 percent (24,520 tons) was classified as old scrap; the largest use of zinc is in galvanizing, from which there is, at present, slight old-scrap salvage. Consumption of old galvanized iron and steel scrap gives steel-furnace flue dust a small zinc content, some of which is recovered by treating the flue dust. The brass scrap used by the brass mills is mostly new scrap and has a high zinc content, which accounts for the high zinc recovery from new copper-base scrap, 117,532 tons, compared with 47,871 tons from old copper-base scrap.

Dealers' buying prices for new zinc clippings averaged 14.27 cents a pound in 1951 compared with 10.38 in 1950 and 7.28 in 1949. The monthly average was 14.75 cents in January 1951 and then increased until it reached 17.75 cents in May. Ceiling prices for zinc scrap became effective June 6. Dealers' prices declined to an average of 12.37 cents for July, August, and September and increased to 12.84 cents in October and to 13.37 cents in December. The changes in the last quarter of 1951 reflected an increase in the ceiling price of

Digitized by Google

new clippings from 14.5 cents to 15.5 cents on October 22 occasioned by an increase in the ceiling price of slab zinc from 17.50 to 19.50 cents a pound on October 2. Average prices for old zinc scrap were 11.12 cents a pound in January, increased to 12.75 cents in May, and declined to 9.64 cents in June with the advent of ceiling prices. The monthly average during the third quarter was 9.12 cents and increased to 10.12 cents in December. The ceiling price for old zinc scrap was increased on October 22 from 11.25 cents to 12.25 cents.

United States imports of old zinc scrap totaled 146 short tons in 1951 compared with 1,633 (revised) tons in 1950. Imported drosses and residues totaled 6,457 tons in 1951 compared with 1,229 tons in 1950. Large quantities of fume from a primary plant in Canada were imported by one company for the manufacture of zinc sulfate and lithopone; the zinc reclaimed from this material was not recorded as secondary zinc, but as recovered from material other than scrap. Exports of zinc scrap were 4,613 tons in 1951 and 6,212 tons in 1950.

Slag—Iron Blast-Furnace

By Oliver S. North

GENERAL SUMMARY

A RECORD output of 29,327,434 short tons was established by the iron blast-furnace slag industry in 1951. Construction of roads, streets, and major airports continued at a high level throughout the year. Screened air-cooled slag used in bituminous construction increased from 4,435,928 short tons in 1950 to 5,973,795 short tons in 1951. Marked increases in tonnages were also shown by screened air-cooled slag aggregates used in highway and airport construction and by expanded slag used as an aggregate for concrete-block manufacture.

Inasmuch as processed-slag stocks are relatively small and constant from year to year, production virtually equals sales, and therefore those terms are used interchangeably in this chapter.

New slag-processing plants at Rockwood, Tenn., and at Duluth, Minn., began operation in 1951. These plants are the only slag-processing facilities active in their respective States.

As shown in table 1, screened air-cooled slag, the principal type used in highway construction, showed an increase in average value of 5 cents (or 4 percent) per ton compared with 1950. This compares to an increase of 8 percent from 1950 to 1951 in overall costs of highway materials.[1]

TABLE 1.—Iron blast-furnace slag processed in the United States, 1947–51, by types

PRODUCTION

The output of slag from iron blast furnaces in 1951 amounted to 38,977,191 short tons compared with 35,886,165 tons reported for the preceding year.

The quantity and value of slag processed for commercial use in 1951, according to reports of processors to the National Slag Association, reached new record highs of 29,327,434 short tons valued at $36,307,693. These totals are 18 and 23 percent above the preceding year's figures of 24,926,033 short tons valued at $29,480,858. The output in 1951 came from 43 companies operating 68 plants for processing air-cooled slag and from 16 plants producing expanded slag. Fourteen plants reported production of granulated slag.

During 1951, iron blast-furnace slag was processed in the following States: Alabama, California, Colorado, Illinois, Indiana, Kentucky, Maryland, Michigan, Minnesota, New York, Ohio, Pennsylvania, Texas, and West Virginia. The majority of the plants are east of the Mississippi River; as in 1950 and other recent years, output in Ohio was greater than in any other State. Alabama and Pennsylvania follow in order. These three States supplied 66 percent of the total tonnage reported for 1951.

TABLE 2.—Iron blast-furnace slag processed in the United States in 1951, by States

[National Slag Association]

	Screened air-cooled			All types		
	Quantity		Value	Quantity		Value
	Short tons	Percent of total		Short tons	Percent of total	
Alabama	5,157,552	22	$5,352,752	6,156,745	21	$6,791,654
Ohio	5,675,671	24	8,025,708	8,078,142	28	9,781,764

Total	23,276,692	100	29,531,983	29,327,434	100	36,307,693

[1] California, Colorado, Illinois, Indiana, Kentucky, Maryland, Michigan, Minnesota, New York, Tennessee, Texas and West Virginia.

PREPARATION

Processed blast-furnace slag is marketed in air-cooled screened, air-cooled unscreened, granulated, or expanded form. About four-fifths of the total is sold as screened air-cooled material, which is produced by allowing molten slag to flow into pits adjacent to the furnace or by transporting it to a slag bank or modified pit and permitting it to solidify under atmospheric conditions. It is then processed in the same manner as are other mineral aggregates.

The remaining one-fifth of the total output is divided about evenly among the other types. Unscreened air-cooled slag is a crushed, ungraded material. Granulated slag is the granular product formed

Digitized by Google

when molten slag is suddenly chilled by immersion in water; it is made by three general methods—pit, jet, and dry granulation processes. Expanded slag is a foamed product formed when molten slag is expanded by applying a limited quantity of water.

TRANSPORTATION

As in past years, virtually the entire tonnage of processed slag in 1951 was moved by rail and truck, with waterway transportation accounting for only 2 percent of the total. As shown in table 3, railroads handled 47 percent and trucks 51 percent—the third successive year that these figures have remained unchanged.

TABLE 3.—Shipments of iron blast-furnace slag in the United States, 1950–51, by method of transportation

[National Slag Association]

Method of transportation	1950		1951	
	Short tons	Percent of total	Short tons	Percent of total

Interplant handling [1]	513,347	----------	399,327	----------
Total processed	24,926,033	----------	29,327,434	----------

[1] This tonnage is used by the processor locally in making such products as concrete block, asphaltic concrete, etc.

CONSUMPTION

Screened air-cooled slag was the major type processed by the industry and constituted 79 percent of the total output of processed slag in 1951. Granulated slag comprised 8 percent, expanded slag 7 percent, and uncreened air-cooled slag 6 percent.

Screened Air-Cooled Slag.—Consumption of screened air-cooled slag again established a new high of 23,276,692 short tons valued at $29,531,983—over 3 million tons more than in 1950, although it represented a slightly smaller percentage of the total slag processed. The use of screened air-cooled slag as aggregate in portland-cement concrete construction, bituminous construction, and highway and airport construction other than portland-cement and bituminous and as railroad ballast consumed 21,076,059 short tons or 91 percent of the total of this type of slag. Other important uses for the material were in the manufacture of concrete block, mineral wool, and built-up roofing and roofing granules.

Unscreened Air-Cooled Slag.—In 1951 the quantity of unscreened air-cooled slag processed totaled 1,732,969 short tons valued at $969,975—increases of 72 and 52 percent, respectively, over the 1950 figures. Approximately half of this material was used as aggregate in highway and airport construction.

Other uses	495,926	509,962	626,912	322,675
Total	23,276,692	29,531,983	1,732,969	969,975

[1] Other than in portland-cement concrete and bituminous construction.

Granulated Slag.—The consumption of granulated slag in 1951 amounted to 2,249,281 short tons—an increase of 4 percent as compared to the 1950 figure. Of this quantity, 53 percent was utilized as a raw material in the manufacture of hydraulic cement, 34 percent was used as road fill, and 7 percent as an aggregate in concrete block.

Expanded Slag Aggregate.—The consumption of expanded slag in 1951 reached 2,068,492 short tons valued at $4,917,091—gains of 21 and 31 percent, respectively, compared to 1950. The bulk of this output was used in concrete-block manufacture, and a small percentage found application as an aggregate in lightweight concrete.

TABLE 5.—Granulated and expanded iron blast-furnace slag sold or used by processors in the United States in 1951, by uses

[National Slag Association]

Use	Granulated		Expanded	
	Short tons	Value	Short tons	Value
Road fill, etc.	765,362	$577,467

Total	2,249,281	[2] 888,644	2,068,492	4,917,091

[1] Data not available.
[2] Excludes value of slag used for hydraulic cement manufacture.

PRICES

Average values per ton for the various types of processed slag in 1951 are shown in table 6. Values for screened air-cooled slag ranged from 94 cents per short ton for railroad ballast to $1.84 for slag used in the roofing industry. Unscreened air-cooled slag values ranged from 35 cents for railroad ballast to $1.00 for material used in the manufacture of mineral wool. Available data on values of granulated

Digitized by Google

slag show a low of 51 cents for "other uses" and a high of $1.29 for agricultural slag. Expanded-slag values ranged from $2.37 when used as an aggregate in concrete block to $2.88 for the "other uses" classification.

TABLE 6.—Average value per short ton of iron blast-furnace slag sold or used by processors in the United States in 1951, by uses

[National Slag Association]

Use	Air-cooled		Granulated	Expanded
	Screened	Unscreened		
Aggregate in:

Road fill, etc			.75	
Other uses	1.03	.51	.51	2.88

[1] Lightweight concrete.
[2] Other than in portland-cement concrete and bituminous construction.

IRON RECOVERY

The recovery of iron by slag processors during 1951 amounted to 368,526 short tons—an increase of 24 percent over the preceding year's figure. Iron is recovered from slag either by magnetic methods or by hand picking; and the material is returned to the furnaces, where it becomes a useful contribution to the iron and steel industry.

EMPLOYMENT

An average per active day of 2,100 plant and yard personnel worked 5,369,000 man-hours in producing processed slag during 1951. This compares with 5,399,500 man-hours and an average per active day of 2,015 plant and yard employees in 1950.

TECHNOLOGY

The Lackawanna plant of the Buffalo Slag Co., Inc., Buffalo, N. Y., utilizes a surge pile between the primary crushing section and subsequent operations to eliminate delays caused by variations in the nature of the rough slag and in the occurrence of iron, necessitating removal before loading transportation equipment.[2]

Slag is being crushed and graded into 10 sizes for use in sand blasting.[3]

Most of the cement being used in constructing a major dam in central France is a slag-base cement manufactured on the job. The slag is shipped dry from Lorraine steel mills, stored in silos, and fed into ball-grinding kilns containing water. These kilns turn out 10 tons per hour of slag ground extremely fine. The material is stored

Digitized by Google

as paste and later pumped to mixers where it is combined with portland cement and the stone aggregates. It is reported to have a low heat of hydration.[4]

A bulletin issued in Scotland described utilization of blast-furnace slags in Europe.[5] Points of interest cited included the use in England of 4 million tons of slag concrete aggregate and railroad ballast in 1949, the latest year for which figures were available. In the same year production of foamed slag was estimated at 60,000 tons and of granulated slag, 40,000 tons. Other highlights mentioned were greater utilization in Germany of granulated material and the wide use in France of slag aggregate in prestressed concrete sections.

Slag-processing plants are in operation at Sydney, Nova Scotia, and Port Colborne, Ontario, Canada. The latter plant, which specializes in expanded slag aggregates, is near Buffalo, N. Y.

Slate

By Oliver Bowles and Nan C. Jensen

GENERAL SUMMARY

PRODUCTION of slate in the United States during 1951 was considerably lower than in 1950. The decline was primarily in sales of granules and flour. Sales of roofing slate gained 4 percent in quantity and 6 percent in value. Gains were confined to the Pennsylvania operations; sales in other regions declined. The average value per square in 1951 was $21.24 compared with $20.75 in 1950.

Mill-stock sales declined slightly in quantity and value from the high record of 1950. The principal decline was in sales of blackboards and bulletin boards. Sales of structural and sanitary slate, electrical slate, billiard-table tops, and vaults and covers increased substantially. School-slate sales declined in quantity but increased in value. Flagstones, including slate employed for walkways, stepping stones, and miscellaneous uses, declined 1 percent in quantity but gained 13 percent in value.

Slate granules and flour are included as part of the slate industry, although they have little connection with dimension slate. Waste slate from quarries producing roofing and mill stock is used to a very limited extent for making granules and flour. Nearly all of the latter products are derived from independent quarries and from rock unsuited for dimension-slate uses. The principal use of granules is for surfacing prepared roofing. Slate flour is used as a filler in paint, roofing mastic, linoleum, and other products.

Sales of granules and flour declined 14 percent in quantity and 21 percent in value in 1951 compared with 1950. The quantity sold was somewhat lower than the average of recent years. The average value per ton was also considerably lower. Figures for sales of all types of granules, including slate, appear in a table in the chapter of this volume on Stone.

SALES

Dimension Slate.—Roofing and mill stock, which are cut to specified sizes and shapes, together with flagging and related products, are classed as dimension slate. Table 2 shows sales of these products for the latest 5-year period.

TABLE 2.—Dimension slate sold by producers in the United States, 1947–51

Digitized by Google

Roofing slate is used chiefly in residential building. It might be expected, therefore, that the sales of this product would follow the trend of construction of new dwelling units. As indicated in figure 1, there was an approximate parallelism from 1935 to 1945, except for the comparative lag in roofing-slate sales from 1939 to 1942. Since 1945 roofing-slate sales have failed to keep pace with the tremendous growth in building construction.

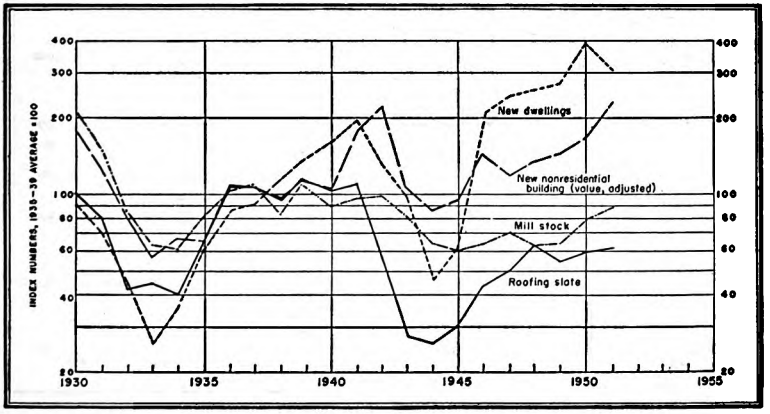

FIGURE 1.—Sales of roofing slate and mill stock compared with number of new dwelling units and value of new nonresidential building, 1930–51. Data on number of new dwelling units (actual starts) in nonfarm areas from U. S. Department of Labor; on value of nonresidential building (adjusted to 1939 prices) from U. S. Department of Commerce and U. S. Department of Labor.

Mill-stock slate is used for blackboards in schools, and for steps, baseboards, and other units in office buildings and other nonresidential structures. Mill-stock sales followed the general trend of nonresidential building construction from 1930 to 1939. As indicated in figure 1, since 1944 mill-stock sales have fluctuated moderately, while nonresidential building activity has advanced and in 1951 exceeded all previous records. Slate evidently is losing ground in the competitive field.

Figure 2 is a graphic presentation of the value of slate sold from 1920 to 1951, by principal uses. Two peaks were reached during this period, one in 1925 and the other in 1950. The two troughs reflect the unfavorable conditions of the depression and World War II.

Granules and Flour.—Sales of granules in 1951 dropped 15 percent in quantity below the alltime high of 1950. The value of sales declined 22 percent. The average sales value per ton f. o. b. plant ($10.35) was 99 cents lower than in 1950. Sales of slate flour declined 11 percent in quantity and value. Granules and flour were produced in Arkansas, California, Georgia, New York, Pennsylvania, and Vermont. Granules but no flour were sold in Maryland and Virginia.

REVIEW BY STATES

As shown in table 1, total production of slate in the United States declined 11 percent in quantity in 1951 compared with 1950. Seventy-seven operators reported production in 1951, a decline of 17 from 1950. Table 4 shows sales of slate in 1951, by State and use.

Maine.—Electrical slate is the principal product of the Maine quarries, which are situated near Monson, Piscataquis County. As in 1950, only one company was active in 1951.

[1] Flagging and similar products, granules, and flour.
[2] Included with "Undistributed" to avoid disclosure of individual company operations.

New York.—There were 2 slate operators less in 1951 than in 1950, and the value of sales declined 29 percent. Flagging, granules, and flour were the principal products.

Pennsylvania.—Lehigh and Northampton Counties are the most productive slate areas in the United States. All types of slate products are made because the "soft-vein," blue-black slate characteristic of these areas is suitable for making blackboards, structural slate, and all other mill-stock types, as well as roofing. Slate produced in York County in the Peach Bottom district on the Maryland-Pennsylvania border in the vicinity of Cardiff, Md., and Delta, Pa., may not be shown separately and therefore is included with Northampton County in table 5, which presents detailed figures for Pennsylvania.

The total value of all slate products sold in Pennsylvania in 1951 increased 3 percent compared with 1950. Gains in roofing and electrical slate, vaults and covers, and billiard-table tops were substantial both in quantity and value. Blackboard and bulletin-board production declined both in quantity and value. Structural and sanitary products gained in quantity but declined in value. Conversely, school slates declined in quantity but increased in value. Other products (principally granules and flour) declined in value. The percentage changes in these items in 1951 compared with 1950 were as follows: Roofing slate, increase of 8 percent in quantity and 15 percent in value; electrical slate, increase of 25 percent in quantity and 34 percent in value; structural and sanitary slate, increase of 16 percent in quantity but a decline of 5 percent in value; blackboards and bulletin boards, decline of 20 percent in both quantity and value; billiard-table tops, increase of 29 percent in quantity and 37 percent in value; school slates, decline of 15 percent in quantity but a gain of 34 percent in value. Vaults and covers is a small item that made

1950	27	124,280	2,341,127	11,050	12,044	849,970	611,004	2,340	2,097

County	Mill stock—Continued						Other uses (value)	Total value
	Blackboards and bulletin boards		Billiard-table tops		School slates			
	Square feet	Value	Square feet	Value	Square feet	Value		
Lehigh	296,120	$139,940	------	------	237,500	$11,943	$12,400	$309,282
Northampton and York [1]	837,650	527,071	207,490	$131,081	------	------	1,578,741	5,379,588
Total: 1951	1,133,770	667,011	207,490	131,081	237,500	11,943	1,591,141	5,688,870
1950	1,420,960	829,510	161,030	95,996	279,100	8,936	1,645,300	5,546,014

[1] York County produced granules and flour only; included with Northampton County to avoid disclosure of individual company operations.

large gains. Slate for other uses declined 3 percent in value. There was a decrease of two in the number of active operators.

Vermont.—To avoid revealing the production of an individual firm, Maine has been included with Vermont in table 4. The total value of slate products sold in these two States in 1951 was 6 percent less than in 1950. Roofing-slate sales declined 1 percent in quantity and 3 percent in value. Mill stock increased 27 percent in quantity and 25 percent in value. The value of slate for other uses declined 12 percent. There was a decline of 9 in the number of operators.

Virginia.—Roofing slate was the principal product of the quarries near Arvonia and Ore Bank, Buckingham County. Small quantities of flagging but no mill stock were made. Roofing-slate sales declined 7 percent in quantity and 4 percent in value in 1951 compared with 1950. Granules were produced in substantial quantities during the year, but details cannot be given without revealing the figures of individual producers.

Other States.—Granules and flour were produced in Montgomery County, Ark., near Glenwood; near Placerville, El Dorado County, Calif.; and near Fairmount, Bartow County, Ga. Granules but no flour were produced near Whiteford, Harford County, Md. Flagging and other products were sold in Mariposa County, Calif.

PRICES

The average value of roofing slate f. o. b. quarry or mill, as reported to the Bureau of Mines, increased 49 cents per square in 1951 to $21.24.

Digitized by Google

In Pennsylvania it was $19.98 per square, in New York $43.51, in Vermont and Maine $21.86, and in Virginia $26.73.

The average value of mill stock was 67 cents per square foot, the same as in 1950. The average value of electrical slate declined 5 cents (to $1.44); structural and sanitary slate declined 8 cents (to $0.67); and vaults and covers declined 9 cents (to $0.83). Blackboards and bulletin boards remained virtually unchanged at $0.59. The average sales value per short ton of granules declined 99 cents (to $10.35), while flour declined 2 cents (to $4.36).

Price History.—The trend in yearly average value of roofing slate and mill stock compared with wholesale prices of all building materials since 1915 is indicated in figure 3. Since 1933 mill-stock prices have followed closely the price trend of all building materials. Roofing-slate prices also maintained a close correspondence with those of all building materials until 1945, but since that date they have advanced much beyond the general average. The contrast between the trend in prices shown in figure 3 and the trend in volume of sales indicated in figure 1 seem to indicate that the relative decline in the quantity of

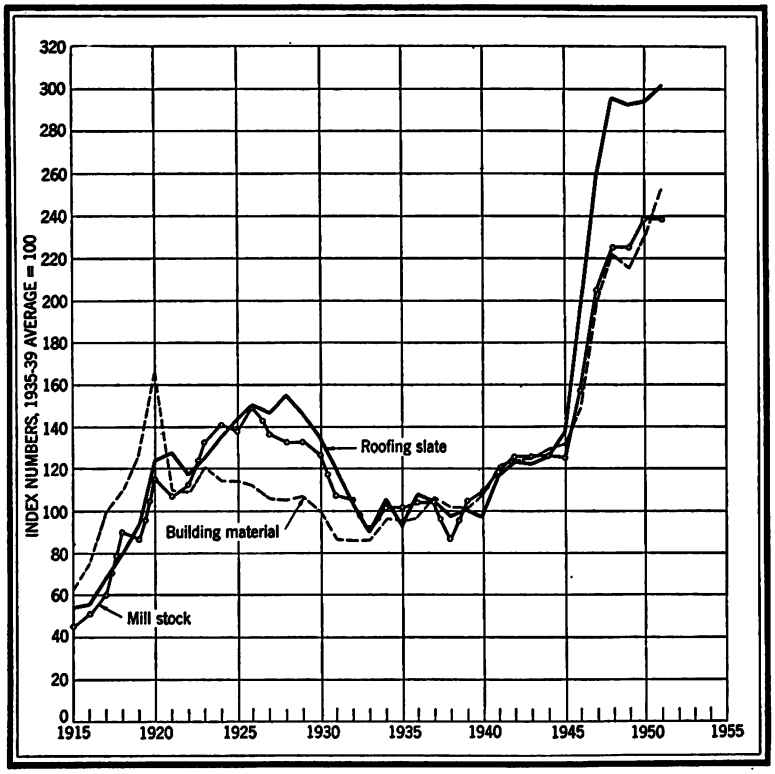

FIGURE 3.—Average value of slate compared with wholesale prices of building materials in general, 1915–51. Wholesale prices from U. S. Department of Labor.

Digitized by Google

roofing slate sold since 1945 is in a large measure related to the relative increase in its price compared to that of other building materials.

FOREIGN TRADE[1]

Imports.—The value of slate imported for consumption, which made remarkable gains in 1950, continued its strong upward trend. As indicated in table 6, the value of imports in 1951 was more than 2½ times as great as in 1950. Most of the imports consisted of school slates from Italy and Portugal. Many of them are imported unframed and are framed in the United States. A factor that may have contributed to this greatly increased movement was the reduction, effective May 30, 1950, of the import duty from 25 percent to 12½ percent ad valorem.

Exports.—Table 7 gives the value of exports of slate products for the latest 5-year period, as reported by shippers to the Bureau of Mines. The total value of exports was 23 percent less in 1951 than in 1950.

TECHNOLOGY

New milling facilities were constructed in Pennsylvania. One roofing-slate mill was modernized by introducing a conveyor-belt system for delivering slate to the various operations.

Pennsylvania State College conducted a time study of unit processes in the Pennsylvania slate industry as a guide toward increasing the efficiency of operations.[2] This college also reviewed the status of slate technology and urged operators to take active measures toward reducing the cost of quarrying and manufacture.[3]

Stone

By Henry P. Chandler and Nan C. Jensen

GENERAL SUMMARY

COMBINED sales of dimension and crushed stone in 1951 were at a record figure of 286 million short tons valued at $438 million. These sales represented a gain of 14 percent in tonnage and 12 percent in value over the preceding year. In the dimension-stone industry during 1951 the gain in sales over 1950 amounted to less than 1 percent in tonnage and 3 percent in value. In the crushed- and broken-stone industry, sales increased 14 percent, both in tonnage and value; gains occurred in nearly all classes of material.

The tables in this chapter give the quantities of stone sold or used by producers (also referred to as sales) and the values f. o. b. quarries and mills. Stone made into abrasives, such as grindstones, and stone used in making cement and lime, are, however, not included herein. They are reported in terms of finished products in the Abrasive Materials, Lime, and Cement chapters. Dimension stone and crushed stone are considered separately, except in introductory tables 1 to 4, which show total sales of stone by kinds, uses, and States.

DIMENSION STONE

The term "dimension stone," as used in this chapter, is applied to blocks and slabs of natural stone, most of which are cut to definite shapes and sizes. Dimension stone is used principally for constructing masonry walls and memorials. Crushed and broken stone consists primarily of irregular fragments sized chiefly by mechanical screening and is used mainly as concrete aggregate, railroad ballast, furnace flux, and agricultural limestone.

Dimension-stone producers may be divided into three main groups on the basis of method of operation. The first group quarries stone and sells it as rough blocks or slabs; the second quarries stone and also manufactures it into finished products; and the third buys sawed slabs or rough blocks of stone and manufactures them into finished products. The Bureau of Mines statistical canvass covers the first and second groups but not the third. Bureau of Mines statistics are compiled from reports of quantities and values of original sales and include some material sold as rough blocks and some sold as finished products.

Total sales of dimension stone (including slate) in 1951 made a very slight increase in quantity and a 3-percent increase in value compared with 1950. These overall figures include slate, but detailed statistics of that branch of the industry appear in the Slate chapter.

TABLE 5.—Dimension stone sold or used by producers in the United States,[1] 1950–51, by kind and use

Kind and use	1950	1951	
		Amount	Percent of change from 1950
Granite:			
Building stone:			
Rough construction, short tons	77,040	74,214	−4
Value	$437,332	$500,133	+14

BUILDING STONE

The largest use of dimension stone is for building purposes. New construction calling for the use of dimension stone in 1951 remained at almost the same level as the previous year. The different kinds of dimension stone used also changed but little. Table 6 gives the quantity and value of the major types of building stone sold or used in 1951.

TABLE 6.—Building stone sold or used by producers in the United States[1] in 1951, by kinds

Kind	Rough				Finished				Total	
	Construction		Architectural		Sawed		Cut		Cubic feet	Value
	Cubic feet	Value	Cubic feet	Value	Cubic feet	Value	Cubic feet	Value		
Granite	893,755	$500,133	252,880	$513,745	329,408	$1,690,875	243,594	$2,857,365	1,719,637	$5,562,118
Basalt	389,245	114,225							389,245	114,225
Marble			284,382	1,043,578	150,965	880,999	348,514	4,735,336	783,861	6,659,913
Limestone	1,218,603	375,826	2,974,089	3,190,344	3,596,607	5,900,851	1,526,014	8,538,882	9,315,313	18,005,903
Sandstone	397,835	157,977	970,893	1,411,276	1,757,386	4,009,842	82,928	650,745	3,209,042	6,229,840
Miscellaneous					[2] 683,694	[2] 2,255,306			683,694	2,255,306
Total	2,899,438	1,148,161	4,482,244	6,158,943	[2] 6,518,060	[2] 14,737,873	2,201,050	16,782,328	16,100,792	38,827,305

[1] Includes Puerto Rico.
[2] Sawed stone corresponds to dressed stone for construction work (walls, foundations, bridges) and cut stone to architectural stone for high-class buildings.
[3] Rough and cut miscellaneous stone included with sawed stone.

GRANITE

Sales of granite in the form of blocks and slabs during 1951 decreased slightly in tonnage, but increased slightly in total value over 1950. The increases occurred in the sales of dressed building material, dressed monumental granite, paving blocks, and curbing, while the sales of rough building and monumental material and rubble decreased. The average value of the granite produced in 1951 was $43.66 a short ton, a 6-percent increase over 1950.

Tables 8 and 9 show sales of monumental granite in the Barre district, Vermont, exclusive of small quantities of Barre granite sold as construction or crushed stone.

Estimated sawing cost	1,408,428	1,445,354	1,359,642
Total value of granite	16,487,450	16,859,867	17,205,793

BASALT AND RELATED ROCKS (TRAPROCK)

Because of their dark color, basalt and related rocks are used to a limited extent as building stone. Sales for rough construction increased and rubble dropped in 1951 from the previous year, the total tonnage declining 12 percent. However, the total value increased 7 percent, and the average value per unit 21 percent. Basalt and related rocks, such as syenites and diorites, are used to some extent for memorials but are classed in the trade as "black granite" and are therefore included with the figures for monumental granite.

TABLE 10.—Basalt and related rocks (traprock) (dimension stone) sold or used by producers in the United States in 1951, by State and use

State	Active plants	Building stone				Total	
		Rough construction		Rubble		Short tons	Value
		Short tons	Value	Short tons	Value

MARBLE

Total sales of marble declined slightly during 1951 in quantity and value over the preceding year. Although small increases were noted in the quantity and value of building stone, material for monuments declined. There was also a 3-percent decrease in unit value. Tables 11 and 12 give sales data on marble, by uses and States.

The Georgia Marble Co., Tate, Ga., announced the purchase by its subsidiary, the Alabama Limestone Co., of the entire physical assets of the Rockwood Alabama Stone Co., 25 miles south of Muscle Shoals, Ala.[1]

TABLE 11.—Marble (dimension stone) sold by producers in the United States, 1950–51, by uses

LIMESTONE

Limestone blocks cut to definite shapes and sizes are used almost exclusively for building purposes, such as interiors and exteriors of public buildings and commercial structures. The total of all types of dimension limestone sold during 1951 changed but little from the previous year. Tonnage declined slightly, while the total and unit values each increased 3 percent. Rough architectural material and rubble gained in tonnage sold, while sales of rough construction material, finished building material, and flagging declined.

The Bedford-Bloomington area, Indiana, continued to produce most of the dimension limestone in the United States, its output being 82 percent of the total rough architectural and finished (sawed and cut) limestone by volume and 76 percent by value. Tables 14 to 16 show production in the Bedford-Bloomington, Ind., and Carthage, Mo., areas over a 5-year period.

SANDSTONE

Sales of sandstone in 1951 increased 10 percent in tonnage and 18 percent in value over 1950. The average unit price also increased 8 percent. Sales of rough architectural stone, sawed dressed building stone, rubble, and curbing gained over the previous year. Losses were noted in rough construction stone, cut dressed building stone, and flagging.

Ohio continued to be the largest producing State, contributing 56 percent of the total. Other States, in order of production, were Tennessee, Pennsylvania, Colorado, and New York.

Table 18 presents the sales of bluestone in 1942–51. Bluestone is a type of sandstone that splits into thin, uniform slabs. It is particularly adapted for flagging but is also used for building stone and curbing. The output in 1951 declined 35 percent in tonnage and 23 percent in value from the previous year.

[1] New York and Pennsylvania were the only producing States.

MISCELLANEOUS STONE

Types of stone other than those included in the major groups already discussed are covered in table 19. The principal types in this classification are mica schist, argillite, light-color volcanic rocks (such as rhyolite), soapstone, and greenstone. The quantity sold increased 7 percent in tonnage and 5 percent in value over 1950, but the unit value declined slightly.

TABLE 19.—Miscellaneous varieties of stone (dimension stone) sold or used by producers in the United States in 1951, by State and use

[2] Approximately 683,694 cubic feet.
[3] Approximately 23,260 cubic feet.

TRENDS IN USE OF DIMENSION STONE

Figure 1 presents a 36-year history of the output of dimension stone, by kinds. The industry declined greatly during depression and war years, but after 1944 the trend was upward. Conditions were substantially the same in 1951 as in 1950.

Figure 2 traces, for a 37-year period, the history of building-stone production as a whole and of the chief variety, limestone, in their relation to nonresidential building, the class of construction using stone most extensively. In peacetime building-stone sales generally follow the trend of nonresidential building, but in 1951 they failed to pace construction, much of which was of types that use stone sparingly.

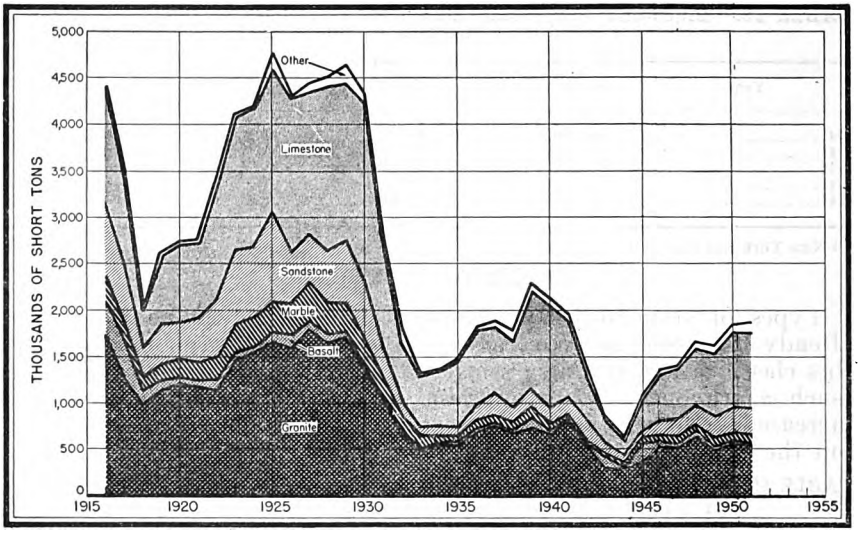

FIGURE 1.—Sales of dimension stone in the United States, 1916–51, by kinds.

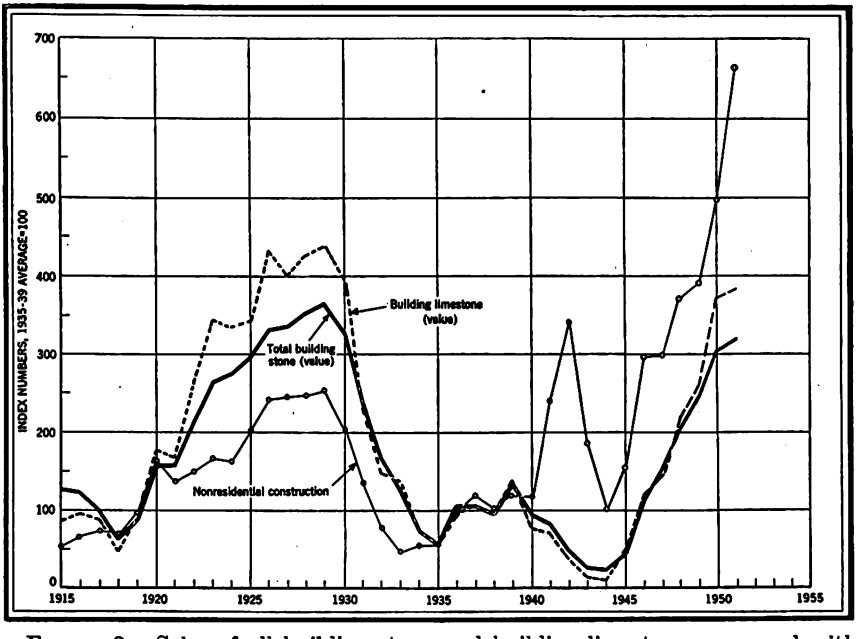

FIGURE 2.—Sales of all building stone and building limestone compared with nonresidential construction (public and private), 1915–51. Data on nonresidential-building construction from Survey of Current Business.

TECHNOLOGY

An exposure test wall of virtually every commercial type of natural stone used in construction was being studied at the National Bureau of Standards.[2]

[2] American Society for Testing Materials, Bull. 171, January 1951, p. 10.

Digitized by Google

The effects of fire on building stones were studied and described.[3] New types of quarrying machinery used in Europe was the subject of a recent article.[4]

Limestone dominates the building-stone industry of Indiana, and granites occupy a leading position in the dimension-stone industry of Minnesota. The stone deposits of these States were described.[5]

CRUSHED AND BROKEN STONE

Sales of crushed and broken stone, in addition to that used for making cement and lime, continued to show an increase in 1951 over 1950, the total being over 284 million short tons at an average value of $1.33 a ton. This represented a 14-percent increase both in tonnage and value over the preceding year. The average unit price remained unchanged.

Tonnage increases were noted for all uses except material for sugar factories, where only a small reduction occurred.

Table 20 shows the quantity sold and the value of the output during 1950 and 1951, by uses. Detailed data on asphaltic stone and slate granules and flour are given in the Asphalt and Slate chapters of this volume.

Tables 21 and 22 show the tonnage and value of stone used for concrete and road metal and for railroad ballast for a series of years and by States for 1951.

TABLE 20.—Crushed and broken stone sold or used by producers in the United States,[1] 1950–51, by principal use

Use	1950			1951		
	Short tons	Value		Short tons	Value	
		Total	Average		Total	Average
Concrete and road metal	147,107,670	$192,293,884	$1.31	169,557,766	$217,373,404	$1.28

COMMERCIAL AND NONCOMMERCIAL OPERATIONS

In contrast with strictly commercial operations, noncommercial operations represent tonnages reported by States, counties, municipalities, and other Government units as being produced by themselves or by contractors for their own consumption. Table 23 shows the production of crushed stone for concrete and road metal during recent years by both types of operations. Noncommercial operations during 1951 gained 16 percent over 1950 compared with a 15-percent gain for commercial ones, continuing the trend of the previous year.

TABLE 23.—Crushed stone for concrete and road metal sold or used by commercial and noncommercial operators in the United States,[1] 1947–51

[Figures for "noncommercial operations" represent tonnages reported by States, counties, municipalities, and other Government agencies, produced either by themselves or by contractors expressly for their consumption, often with publicly owned equipment; they do not include purchases from commercial producers. Figures for "commercial operations" represent tonnages reported by all other producers.]

Year	Commercial operations				Noncommercial operations				Total	
	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Percent of change in quantity from preceding year

[1] Includes Alaska, Hawaii, and Puerto Rico.

GRANULES

The output of granules for roofing purposes has been canvassed since 1942. Table 24 shows total production and value for the past 5 years. Separate figures for slate granules are given in the Slate chapter of this volume.

TABLE 24.—Roofing granules[1] sold or used in the United States, 1947–51, by kinds

Year	Natural		Artificially colored		Brick		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1947	504,980	$4,166,810	1,133,870	$17,559,227	56,570	$998,434	1,695,420	$22,724,471

SIZE OF PLANTS

Although the number of crushed-stone plants in the United States declined some 5 percent during 1951, the average plant production increased 19 percent over the 1950 output to approximately 168,000 tons. During 1951, 416 plants producing annually less than 25,000 tons each supplied less than 2 percent of the output. On the other hand, the 43 plants that produced over 900,000 tons each contributed nearly 30 percent of the total. Table 25 shows additional details of the size pattern of the industry.

TABLE 25.—Number and production of commercial crushed-stone plants in the United States in 1950–51, by size of output [1]

Size of output	1950				1951			
	Number of plants	Total production of plants (short tons)	Percent of total	Cumulative total (short tons)	Number of plants	Total production of plants (short tons)	Percent of total	Cumulative total (short tons)
Less than 1,000 tons	49	22,950	0.01	22,950	48	18,249	0.01	18,249

[1] Exclusive of marble which is primarily a dimension-stone industry. Includes Alaska, Hawaii, and Puerto Rico.

METHODS OF TRANSPORTATION

Transportation methods used by the crushed-stone industry in 1951 changed very little from the preceding year, only a slight increase percentagewise being noted in the tonnage moved by rail. Waterways provide relatively minor but locally important transportation facilities.

TABLE 26.—Crushed stone sold or used in the United States [1] in 1951, by method of transportation

Method of transportation	Commercial operations		Commercial and noncommercial [2] operations

GRANITE

Although the tonnage of crushed and broken granite sold in 1951 declined 7 percent and its value 5 percent from 1950, the average unit price advanced 2 cents a ton to $1.36. The material assigned to "other uses" gained, but all other uses reported losses both in tonnage and value. North Carolina was the principal producing State, followed by Georgia, South Carolina, California, and Virginia, in that order.

BASALT AND RELATED ROCKS (TRAPROCK)

Commercial traprock normally includes basalt, gabbro, diorite, and other dark igneous rocks. It is widely used for concrete, road metal, and railroad ballast, and to a lesser extent for riprap and such "other uses" as fill material, roofing granules, etc. The sales of crushed and broken traprock in 1951 were 28 percent greater in quantity and 25 percent greater in value than in 1950. Sales of riprap and of material assigned to "other uses" declined both in tonnage and value, while sales of crushed material for concrete and road metal and for railroad ballast increased. The average value declined slightly from the preceding year to $1.46 a short ton. New Jersey was the leading producer, followed by Oregon, Washington, and Pennsylvania, in that order.

MARBLE

Large quantities of waste material, consisting either of defective blocks or cuttings and spalls from marble-dressing operations, accumulate in the processing of marble blocks. This byproduct material is marketed for a great variety of uses (*see* footnote 1, table 27). The average value varies from State to State, because in certain States a large proportion of this material is marketed for such high-priced products as terrazzo or marble flour, whereas in other States a considerable amount is sold for roadstone, concrete aggregate, or other relatively low-priced uses. The average unit value for crushed and broken marble was $10.27, an increase of $1.69 over the preceding year.

TABLE 27.—Marble (crushed and broken stone) sold by producers in the United States in 1951, by States [1]

State	Active plants	Short tons	Value	State	Active plants	Short tons	Value
Alabama	2	(2)	(2)	Tennessee	4	21,444	$145,438
Arkansas	1	250	$1,000	Texas	1	10,675	303,500

LIMESTONE

Because of its wide distribution, chemical and physical properties, and relatively moderate production cost, limestone is used in the United States more than any other type of stone. Sales of limestone were reported to the Bureau of Mines from 44 States and 2 Territories in 1951. In 1951 limestone (excluding that used in manufacturing cement and lime) constituted 72 percent of the total crushed and broken stone produced in the United States. Sales of riprap decreased slightly, but sales of all other classifications of limestone increased during 1951, the tonnage of the total sales being nearly 14 percent higher than in 1950. The total average unit value increased 2 cents a ton to $1.32.

Details by States and uses are shown in table 30, and the quantities and values of limestone applied to miscellaneous uses are indicated in table 31.

Refractory (dolomite)	1,040,530	1,216,933	1,112,186	1,519,831
Road base	1,344,400	1,157,231	1,484,602	1,309,597
Stucco, terrazzo, and artificial stone	73,130	762,889	80,244	800,266
Sugar factories	717,620	1,608,007	563,064	1,369,475
Other uses [4]	1,031,270	1,550,805	1,395,343	2,201,926
Use unspecified	394,690	529,164	806,509	1,034,891
Total	17,081,140	31,979,462	20,438,880	38,702,831

[1] Includes Hawaii and Puerto Rico.
[2] Includes stone for filler for calcimine, caulking compounds, ceramics, chewing gum, explosives, floor coverings, foundry compounds, glue, grease, insecticides, leather goods, paint, paper, phonograph records, picture-frame moldings, plastics, pottery, putty, roofing, rubber, toothpaste, wire coating, and unspecified uses. Excludes limestone whiting made by companies from purchased stone.
[3] Includes stone for refractory magnesia.
[4] Includes stone for acid neutralization, athletic-field marking, carbon dioxide, chemicals (unspecified), concrete blocks and pipes, fill material, oil-well drilling, patching plaster, rayons, roofing granules, spalls and water treatment.

Dolomite (calcium-magnesium carbonate) has a variety of uses, some quite distinct from those of high-calcium limestone. Dead-burned dolomite is used as a refractory lining for metallurgical furnaces; statistical data on this product (which is closely allied to lime) are given in the Lime chapter of this volume. Raw dolomite is also used as a refractory, particularly for patching furnace floors.

Sales of dolomite and its primary calcined product, dolomitic lime, are listed by consuming industry, in table 32.

TABLE 32.—Dolomite and dolomitic lime sold or used by producers in the United States for specified purposes, 1950–51

	1950		1951	
	Short tons	Value	Short tons	Value
Dolomite for—				
Basic magnesium carbonate [1]	236,480	$409,852	363,883	$725,791
Refractory uses	1,040,530	1,216,933	1,112,186	1,519,831
Dolomitic lime for—				
Refractory (dead-burned dolomite)	1,759,440	21,725,560	1,966,460	26,375,313
Paper mills	55,000	642,000	46,000	584,000
Total (calculated as raw stone) [2]	4,906,000	----------	5,501,000	----------

[1] Includes dolomite for refractory magnesia.
[2] 1 ton of dolomitic lime is equivalent to 2 tons of raw stone.

Table 33 shows the tonnages and values of fluxing stone sold for use in various metallurgical operations.

TABLE 33.—Sales of fluxing limestone in the United States, 1947–51, by uses

Year	Blast furnaces		Open-hearth plants		Other smelters [1]		Other metallurgical [2]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1947	25, 817, 270	$22, 000, 942	6, 059, 440	$5, 862, 292	512, 880	$593, 811	180, 680	$230, 905	32, 570, 270	$28, 687, 950
1948	26, 339, 790	24, 721, 052	7, 873, 410	8, 695, 137	503, 490	609, 354	185, 250	224, 465	34, 901, 940	34, 250, 008
1949	23, 768, 970	24, 127, 897	5, 922, 020	6, 929, 134	728, 960	835, 962	332, 370	374, 649	30, 752, 320	32, 267, 642
1950	28, 397, 710	29, 222, 700	6, 936, 900	7, 948, 041	457, 630	587, 643	177, 580	174, 004	35, 969, 820	37, 932, 388
1951	32, 007, 284	35, 941, 217	6, 784, 102	8, 279, 021	842, 877	992, 651	295, 694	409, 236	39, 929, 957	45, 622, 125

[1] Includes flux for copper, gold, lead, zinc, and unspecified smelters.
[2] Includes flux for foundries and for cupola and electric furnaces.

The statistics of the lime and cement industries are presented in separate chapters of Minerals Yearbook and are not covered in the Stone chapter; however, a commodity review of limestone would be incomplete without suitable recognition of the large tonnage of limestone consumed by these industries. Consequently, table 34 shows the total tonnage consumed for all purposes.

TABLE 34.—Limestone sold or used for all purposes in the United States,[1] 1949–51, in short tons

Use	1949	1950	1951
Limestone (as given in this report) (approximate)	163, 746, 000	180, 919, 000	205, 480, 000
Portland and natural cement and cement rock [3]	55, 219, 000	59, 361, 000	64, 284, 000
Lime [4]	12, 637, 000	14, 980, 000	16, 511, 000
Total	231, 602, 000	255, 260, 000	286, 275, 000

[1] Includes Hawaii and Puerto Rico.
[3] Reported in terms of cement in Cement chapter of this volume.
[4] Reported in terms of lime in Lime chapter of this volume.

SANDSTONE

Although the sales of crushed and broken sandstone in 1951 decreased 4 percent in tonnage from the previous year, the total value increased slightly, and the average unit value increased 9 cents a ton to $2.09. Decreases were noted in the sales of sandstone for riprap and concrete and road metal, while increases occurred in the sales of refractory stone, railroad ballast, and the material assigned to "other uses."

MISCELLANEOUS STONE

Crushed and broken stone, other than the five principal varieties already discussed, includes light-color volcanic rocks, schists, boulders from river beds, serpentine, chats, and flint. Table 36 shows the total sales of all these miscellaneous kinds of stone by their end uses. Sales during 1951 increased 30 percent in tonnage and 26 percent in value compared with 1950, but the average unit value decreased 3 cents to 85 cents a ton. California was the largest producer in 1951, followed by Oregon, Missouri, and Oklahoma, in that order.

MARKETS

As crushed stone is used principally as an aggregate in concrete, its sales tend to parallel cement shipments and the area of concrete pavements. These relationships are indicated in figure 3. Although construction declined slightly in 1951 compared with 1950, the sale of crushed stone for all purposes continued its advance, as in the previous 5 years.

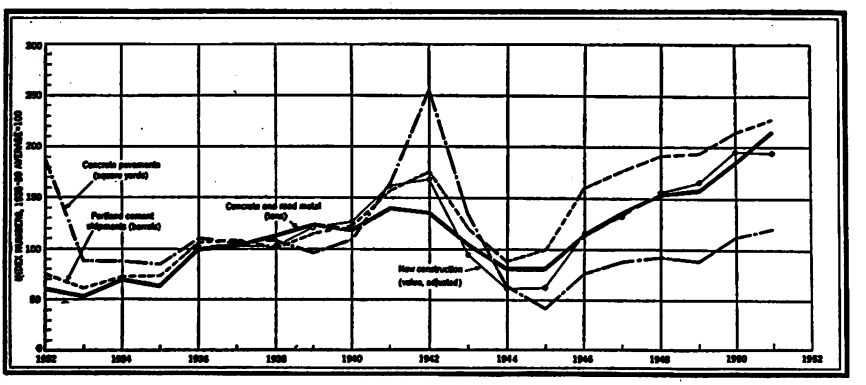

FIGURE 3.—Crushed-stone aggregates (concrete and road metal) sold or used in the United States compared with shipments of portland cement, new construction (value, adjusted to 1939 prices), and concrete pavements (contract awards, square yards), 1932–51. Data on construction and concrete pavements from Survey of Current Business.

The metallurgical industries in 1951 operated at a higher level than in 1950, and 1951 was a record year in the total sales of fluxing limestone, as shown in figure 4.

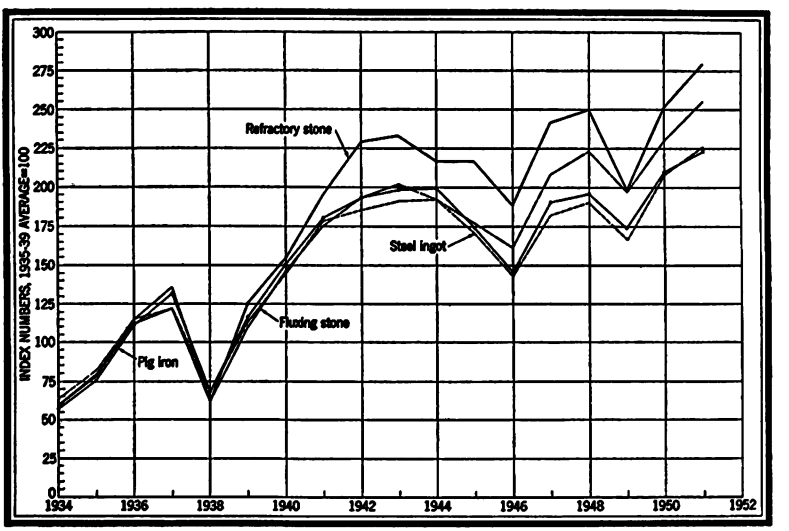

FIGURE 4.—Sales (tons) of fluxing stone and refractory stone (including that used in making lime) compared with production of steel ingot and pig iron, 1934–51. Statistics of steel-ingot production compiled by American Iron and Steel Institute.

TECHNOLOGY

Mining methods received considerable attention in the technical press. One article described underground limestone mining.[6] Another gave operating details designed to increase production of smaller quarries and portable crushing plants.[7] New methods of mining and transporting crushed and broken stone were the subject of a recent publication.[8] Recovery of fines from a limestone crushing plant assures a new source of agricultural limestone.[9]

Much has been written on the chemical and physical characteristics of limestones and dolomites. Some recent contributions in this field of study have been summarized.[10] Spectrographic analyses are important aids in such investigations.[11]

A method was devised for freeze-proofing agricultural limestone to facilitate spreading during cold weather.[12]

Descriptions, illustrated with maps, of limestone deposits in certain Eastern and Midwestern States, were published.[13]

Several new operations were described. A high-grade sandstone suitable for glass manufacture was being developed 10 miles south of Ottawa, Canada.[14] A high-calcium limestone deposit was being quarried near Batesville, Ark., to supply the Alcoa alumina plant at Bauxite, Ark.[15] Modern methods employed in producing and transporting the output of a large metallurgical limestone deposit were described.[16]

FOREIGN TRADE[17]

The importation of stone into the United States in 1951 increased in total value 49 percent over 1950. Increases in both quantity and value occurred in nearly every classification.

Export trade in 1951, covering marble and other building and monumental stone, increased 61 percent in volume and 55 percent in value over 1950. "Other manufactures of stone" decreased 20 percent in value.

Sulfur and Pyrites

By G. W. Josephson and F. M. Barsigian [1]

GENERAL SUMMARY

DURING 1951 the sulfur industry was concerned primarily with solving the shortage problem that had become acute in 1950. Production of Frasch sulfur increased to a record 5,278,000 long tons—2 percent more than in 1950. Sales, however, were lower than in 1950 because producers' stocks had been reduced in 1950 to such a point that further drafts upon them were considered to be unwise. During 1951, however, it was possible to add to such stocks, and they increased 7 percent.

TABLE 1.—Salient statistics of the sulfur industry in the United States, 1935–39 (average) and 1948–51, in long tons

	1935–39 (average)	1948	1949	1950	1951
Native sulfur:					
Production (from Frasch mines)	2,175,057	4,869,210	4,745,014	5,192,184	5,278,249

Imports	433,485	107,411	120,937	208,766	221,487
Recovery as byproduct:					
Production of byproduct sulfuric acid (basis, 100 percent) at Cu, Zn, and Pb plants	504,280	572,719	511,854	661,529	736,672
Production of recovered elemental sulfur (basis, 100 percent S)	[3]	44,369	56,781	142,475	184,013
Other byproduct sulfur compounds (basis, 100 percent S)	[4]	25,792	37,935	[5] 41,963	59,613

[1] Represents mine shipments.
[2] Mine stocks only.
[3] Data not available. In 1939, 4,307 long tons was produced.
[4] Data not available. In 1939, 13,000 long tons was recovered.
[5] Revised figure.

Domestic production of pyrites increased during 1951, as did the output from the various other sources of primary sulfur. Pyrite (sulfur content) increased 10 percent; smelter acid, 11 percent; recovered elemental sulfur, 29 percent, and other byproduct-sulfur compounds, 42 percent. Total United States sulfur production increased from 5,986,000 long tons in 1950 to 6,197,000 in 1951.

International trade continued to be an important factor in the sulfur industry. As foreign demand was greater than United States

[1] Figures on imports and exports compiled by M. B. Price and E. D Page, of the Bureau of Mines, rom records of the U. S. Department of Commerce.

Digitized by Google

sources could supply, a sulfur committee was established in the International Materials Conference to assist in arranging for equitable distribution. Exports declined from 1,479,000 long tons in 1950 to 1,312,000 in 1951.

To assist and encourage the development of new production capacity, the Government, under the provisions of the Defense Production Act, offered incentives such as rapid tax amortization, various types of loans, and priorities on scarce materials. Prices were under the control of the Office of Price Stabilization. Both exports and domestic consumption were placed under direct control of Government agencies.

The year 1951 was particularly noteworthy for the vigorous production-expansion programs that were initiated, both in the United States and abroad. Progress was made on the development of several new Frasch mines and a large number of sulfur-recovery plants processing petroleum gases. A number of new projects were also in progress that would increase the output of pyrites, smelter acid, and other sulfur raw materials. These projects, if all brought to completion, would contribute several million tons of additional production capacity. There was no doubt that a considerable fraction of these projects would actually be completed; however, announcement of new Frasch mines, particularly the large deposit at Garden Island Bay in Louisiana, discouraged development of some of the more marginal projects. The cost disadvantages of most of the alternative sulfur materials continued to retard their rates of development.[2]

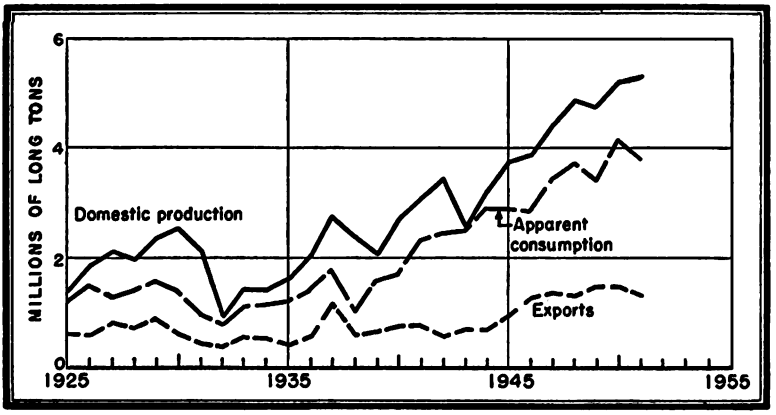

FIGURE 1.—Domestic production, apparent consumption, and exports of native sulfur, 1925-51.

SULFUR

DOMESTIC PRODUCTION

United States production of native sulfur from Frasch process mines in 1951 increased to a new record, 2 percent greater than in 1950, the previous record year. As shown in table 2, a small tonnage of native sulfur was also produced from shallow deposits that cannot

[2] Mining Engineering, Sulfur: Vol. 3, No. 5, May 1951, pp. 403-409.

Digitized by Google

be mined by the Frasch process. This material is generally of lower grade than crude Frasch sulfur and is used principally for treating alkaline soils. Of the total production of United States native sulfur, Texas contributed 75 percent and Louisiana almost 25 percent; minor quantities came from California, Nevada, and Wyoming.

The development of new sulfur production capacity was encouraged by the United States Government through various incentives, such as rapid tax amortization, purchase contracts, priority assistance, exploration loans, and other forms of loans that could be provided under the Defense Production Act by a number of agencies, including the Defense Production Administration, the National Production Authority, the Petroleum Administration for Defense, and the Defense Minerals Administration. During the year the responsibilities of the Defense Minerals Administration were divided between two new organizations. Exploration activities were assigned to the Defense Minerals Exploration Administration, and development and purchase responsibilities were placed under the Defense Materials Procurement Agency.

TABLE 2.—Production of sulfur and sulfur-containing raw materials by producers in the United States, 1950–51, in long tons

	1950		1951	
	Gross weight	Sulfur content	Gross weight	Sulfur content
Native sulfur or sulfur ore:				
From Frasch-process mines	5,192,184	5,192,184	5,278,249	5,278,249
From other mines	3,327	1,072	3,945	1,365
Total native sulfur	5,195,511	5,193,256	5,282,194	5,279,614
Recovered elemental sulfur:				
Brimstone	139,731	139,352	182,495	181,935
Paste	6,452	3,123	4,614	2,078

1951	3,945	3,945	75,609

[1] 1947–48: California, Colorado, Nevada, and Texas; 1949–51: California, Colorado (1949 only), Nevada and Wyoming.

Several firms were conducting research on processes for recovering high-purity sulfur from native sulfur ores that cannot be processed by the Frasch method.[3]

California.—The only sulfur production in California in 1951 came from the Crater deposit in the Last Chance Mountains in Inyo County. The deposit was operated by R. E. Kitching (Inyo Soil Sulphur Co.), 310 Pacific St., Bakersfield, Calif. The Anaconda Copper Mining Co., 25 Broadway, New York, N. Y., prepared to begin production of elemental sulfur at the Leviathan mine in Alpine County. Sulfur from this deposit was to be used by this company in a new copper operation in Nevada. A report on sulfur reserves and production in the State had been published in 1950 by the California Division of Mines.[4]

Louisiana.—Frasch-sulfur production in Louisiana attained a new record of 1,311,293 long tons in 1951, of which 1,271,805 was produced at the Grande Ecaille mine by the Freeport Sulphur Co. In June 1951 Jefferson Lake Sulphur Co. brought Starks Dome into production, and during the year output from this new operation totaled 39,488 long tons. Freeport Sulphur Co. announced that exploration had proved the existence of a large deposit of sulfur at Garden Island Bay Dome at the mouth of the Mississippi River. The company began preparing to construct a sulfur-mining plant having a capacity of 500,000 tons of sulfur annually. Completion of the plant was scheduled for 1953. This company also made progress in the construction of a sulfur mining plant at Bay Ste. Elaine Dome, about 60 miles southwest of New Orleans. Both of these domes are in coastal marsh land, and a large part of the sulfur area of Bay Ste. Elaine is under water. A marine form of mining was to be used at Bay Ste. Elaine.

Nevada.—Native sulfur ore was produced at the Vitallo mine, owned by W. S. Peterson, at Sulphur in Humboldt County. This property was leased during the year to the Black Rock Desert Minerals Co.

Texas.—Sulfur was produced in Texas in 1951 by Duval Sulphur & Potash Co. at Orchard Dome, Fort Bend County; Freeport Sul-

phur Co. at Hoskins Mound, Brazoria County; Jefferson Lake Sulphur Co., Inc., at Clemens Dome, Brazoria County, and Long Point Dome, Fort Bend County; and Texas Gulf Sulphur Co. at Boling Dome, Wharton County, and Moss Bluff Dome, Liberty County. By the end of 1951 construction of a new sulfur plant by Texas Gulf Sulphur Co. at Spindletop Dome near Beaumont, Tex., was nearing completion, and expansion of capacity at Moss Bluff Dome had been initiated. Freeport conducted a drilling program at Nash Dome and established the existence of a small deposit of sulfur on the property.

TABLE 5.—Sulfur produced in Texas in 1951, by companies, in long tons

Company	First quarter	Second quarter	Third quarter	Fourth quarter	Total
Texas Gulf Sulphur Co	800, 244	738, 272	835, 677	772, 608	3, 146, 801
Freeport Sulphur Co	70, 765	69, 055	75, 820	68, 280	283, 920
Jefferson Lake Sulphur Co., Inc	62, 618	84, 927	83, 347	85, 343	316, 235
Duval Sulphur & Potash Co	55, 805	54, 150	50, 700	59, 345	220, 000
Total	989, 432	946, 404	1, 045, 544	985, 576	3, 966, 956

Utah.—No production of sulfur was reported by Western Sulphur Industries at Sulphurdale in 1951, but this firm was preparing to bring the deposit into production.

Wyoming.—Wyoming Gulf Sulphur Co. produced sulfur ore near Cody, Park County. It was reported that this company took possession of the Cody Sulphur Co. property in February 1951. The Continental Sulphur & Phosphate Corp. continued its exploration of the sulfur deposit in Sunlight Valley. A sulfur deposit at Thermopolis, Wyo., was explored by Kenneth L. Porter.

RECOVERY AS BYPRODUCT

As shown in table 2, the bulk of United States supplies of sulfur comes from deposits of native sulfur and pyrites. The native-sulfur and much of the pyrites tonnage is produced as a primary product; but byproduct pyrites, recovered as flotation concentrates in the milling of copper, zinc, and lead ores, constitutes a substantial fraction of the supply. A relatively small tonnage of coal brasses is also obtained as a byproduct at a midwestern coal-washing plant. This byproduct pyrite is included in the statistics of the pyrites section of this chapter.

At metal sulfide smelters, where large volumes of sulfur-bearing gases are released, a portion is recovered in the form of sulfuric acid. Smelter acid produced in 1951 contained 240,800 long tons of sulfur, 11 percent more than in 1950. Table 6 shows the output of acid at smelters during the past 5 years. Further expansions of smelter acid capacity were planned by American Smelting & Refining Co. at Garfield, Utah; Corpus Christi, Tex.; and Amarillo, Tex.; and by the American Zinc, Lead, & Smelting Co. at Fairmont City, Ill., and Dumas, Tex.

Many other industrial operations also produce sulfurous fumes, and in some instances they are sufficiently concentrated to permit commer-

cial recovery of a sulfur byproduct. The sulfur shortage provided a strong impetus to the increase of sulfur recovery operations. Table 1 indicates the progress that had been made in recent years, and in 1951 additional plants were either in the planning or construction stage.[5] By the end of 1951 about 20 plants for the recovery of natural and refinery gases were projected. A number of operations that process coke-oven and other coal gases were active, but there was little interest in new projects. A total of 184,013 long tons of elemental sulfur was recovered in 1951 at gas-processing plants. Shipments totaled 193,780 long tons, of which 191,155 tons was in the form of brimstone and 2,625 in the form of paste. In addition, 59,613 tons of equivalent sulfur was recovered in the form of sulfur dioxide and of hydrogen sulfide, which were used principally for making sulfuric acid.

CONSUMPTION AND USES

Demand for sulfur, particularly of the Frasch variety, was considerably greater than supply in 1951. In the first 5 months of the year suppliers reduced shipments to consumers, in some instances as much as 20 percent below the 1950 rate. The shortage caused a great furor, both in the United States and abroad, as consuming firms became concerned over their current supply positions and future

Smelter acid production	212,000	187,000	167,000	216,000	240,800
Other production[2]	20,600	25,800	37,900	[3] 42,000	59,600
Total	4,219,500	4,426,800	4,093,400	[3] 4,988,100	4,819,200

[1] Crude sulfur or sulfur content.
[2] 1947–49, hydrogen sulfide; 1950–51, hydrogen sulfide and liquid sulfur dioxide. In addition, a quantity of acid sludge was converted to H_2SO_4, but is excluded from the above figures.
[3] Revised figure.

One of the most serious aspects of the problem was achievement of equitable distribution of available supplies, which became a subject of top diplomatic negotiation. In the circumstances, Government control of both exports and domestic consumption became necessary in the United States. Domestic consumption was placed under control by the National Production Authority.

From June 1, 1951, until the end of 1951, Order M–69 limited domestic consumption to 100 percent of the 1950 rate, with certain exceptions. The exceptions to this order were for special defense and essential civilian requirements that had to be supported at higher levels and for the relief of unusual cases of hardship. On November 9, 1951, consumers were limited to a 25-day inventory. At the end of the year (January 1, 1952) Order M–69 was amended to restrict sulfur consumption to 90 percent of 1950 usage.

As indicated in tables, 7, 8, and 9, the general result of the conditions prevailing in 1951 was lower consumption than in 1950. A portion of the decline shown in tables 7 and 8 was due to stockpiling of relatively small quantities by consumers during 1950.

In spite of the shortage, sulfur-consuming capacity was expanded considerably during 1951, because many high-priority projects required additional acid that could be supplied most efficiently from new acid-production facilities.

Although it was generally agreed that the real solution of the shortage lay in the development of new sulfur-production capacity, conservation and alternate raw materials also received much attention.[7] For the first time, the fertilizer industry gave really serious consideration to the possibility of installing large capacity for superphosphate production by methods in which nitrogen compounds are substituted for sulfuric acid. Development of such a trend on a major scale could very substantially modify the markets for sulfur over a period of years.[8]

Consumption statistics compiled by the National Production Authority for 1950 and 1951 provide somewhat greater detail on use

patterns than is available for previous years. These data are tabulated in tables 9 and 10.

The geographic distribution of sulfur consumption is indicated in table 11 which gives data on sulfuric acid production compiled by the United States Department of Commerce. Approximately three-quarters of the total sulfur is converted into sulfuric acid.

TABLE 9.—Sulfur consumed in nonacid uses in the United States, 1950–51, in long tons

[U. S. Department of Commerce, National Production Authority]

Use	1950	1951	Use	1950	1951
Carbon disulfide	191,000	216,000	Miscellaneous	63,000	63,000
Pulp and paper	402,000	387,000			
Crude ground	291,000	270,000	Total	1,042,000	1,030,000
Other chemicals	95,000	94,000			

TABLE 10.—Sulfuric acid [1] (basic, 100 percent) consumed in the United States, 1950–51, by industries, in thousands of short tons

[U. S. Department of Commerce, National Production Authority]

Industry	1950	1951	Industry	1950	1951
Fertilizers:			Rayon and cellulose film	669	685
Superphosphate	3,790	3,943	Synthetic detergents	201	218
Ammonium sulfate	1,510	1,156	Dyes	195	201
Chemicals	2,072	2,507	Textile finishing	37	31
Petroleum and its products	1,679	1,868	Miscellaneous	1,284	1,495
Pigments (Pb, Zn, and Ti)	1,325	1,332			
Iron and steel	1,026	952	Total	13,999	14,632
Other metallurgical	211	244			

[1] Includes virgin, fortified, and spent acid. Fortified and spent acids totaled 2,006,000 short tons in 1950 and 2,433,000 tons in 1951.

STOCKS

After declining steadily since 1942, producers' stocks in 1950 had reached a level lower than was desirable from the standpoint of national defense and industry operating practice. High production rates and consumption-control regulations combined to permit an increase in stocks of approximately 180,000 tons during 1951. At the end of the year producers' stocks totaled 2,837,432 long tons, of which 2,678,261 tons was held at mines.

PRICES

In 1951 sulfur prices were frozen by the Office of Price Stabilization, under the provisions of the General Ceiling Price Regulation, at levels prevailing during the base period (December 19, 1950, to January 25, 1951). For domestic consumption Frasch sulfur was priced between $21 and $24 f. o. b. mines. Export prices ranged from about $25 to $27 at the port.

Recovered sulfur prices varied widely. At a few locations that were in production during the base period prices were frozen at the base level. For example, one plant had an f. o. b. price of $27.50. The Office of Price Stabilization permitted new plants that were not

Digitized by Google

in production during the base period to quote delivered prices at figures that would equal $21 per long ton plus the cost of transportation from the appropriate Frasch mine to the consumer's plant. These prices, therefore, were competitive with the cheapest Frasch sulfur.

In contrast to the above figures, prices in many foreign countries skyrocketed. Many sales at over $100 per ton were reported, and there were rumors of some sales that exceeded $200.

In view of the shortage, it is not surprising that considerable upward pressure on prices developed during 1951. The existence of some black-market activity was indicated by a few rumors of domestic sales at prices ranging up to $100 per ton. However, the tonnage involved apparently was insignificant, and in general the controlled price structure was observed in the United States.[9]

The price of sulfur had not risen as much as has the general level of retail and wholesale prices since 1935–39. The industry felt the need for a readjustment upward, part of the justification being that an increase in crude-sulfur prices would help to stimulate production from marginal sources of supply.[10]

FOREIGN TRADE

As indicated in the section on consumption, foreign demand for Frasch sulfur was very active in 1951. Before the United States Government established quotas, the rate of export was so far below demand that it had become a diplomatic problem.

A Sulphur Committee was organized as a unit of the International Materials Conference to achieve equitable distribution of available supplies during the period of shortage and encourage expansion of production capacity. The committee collected statistical information from all Free World producing and consuming countries to determine overall supplies and requirements. After a system of factoring had been applied the proposed quotas for each of the importing nations were determined, as well as the exports that would be needed from each of the supplying nations. In general, the distribution patterns proposed by the committee were followed by the exporting countries. The first report of the committee estimated that world demand exceeded world supply by about 1,000,000 tons and called for a general increase of production capacity throughout the world. Conservation also was stressed as being a possible means of improving the situation.

As shown in table 12 and 13, crude-sulfur exports from the United States were 11 percent lower in 1951 than in 1950, and exports of processed sulfur were also much lower.

Imports of sulfur, shown in table 12, were very small.

An agreement was reached between Texas Gulf Sulphur Co. and Freeport Sulphur Co., to terminate the activities of the Sulphur Export Corp. After shipments to fulfill allocations for the first quarter of 1952 were completed, exports were to be handled directly by the individual companies.

WORLD REVIEW

The shortage stimulated a great deal of discussion, planning, and actual development of new facilities for the production of sulfur throughout the world.

To preserve available stocks and new supplies for the most important uses in each country most Federal Governments maintained a system of control over the distribution and consumption of sulfur.

As shown in table 14, the bulk of world native sulfur output comes from only a few countries, but small quantities are produced in many others. It is estimated that the world output totaled over 5,800,000 long tons in 1951.

In addition to the native sulfur, it is estimated that the ouput of other elemental sulfur, principally from gas-purification operations and pyrites processing, exceeded 400,000 long tons. World ouput of elemental sulfur therefore totaled well over 6,200,000 tons in 1951.

[3] Data not available; estimate by author of chapter included in total.
[4] Estimate.
[5] In addition the following tonnages of ground sulfur rock (30 percent S) were produced and used as an insecticide: 1946, 12,592 tons; 1947, 18,716 tons; 1948, 15,176 tons; 1949, 19,213 tons; 1950, 15,778 tons; 1951, 22,120 tons.

Canada.—Canada need not suffer a sulfur shortage for any extended period because very large resources are available within its own borders. Various processes and sources of supply were being developed.[11] Native sulfur deposits were being investigated by Sunbeam Sulphur, Ltd., a subsidiary of Dominion Tar & Chemical Co., about 100 miles north of Edmonton in Alberta.[12]

Shell Oil Co. was proceeding with development of a plant to recover about 10,000 tons of sulfur annually from sour gas in the Jumping Pound field of Alberta.

Canadian Industries, Ltd., was constructing a plant at Copper Cliff, Ontario, to recover liquid sulfur dioxide from the stack gases of a new flash-smelting copper furnace of International Nickel Co. As the ore is smelted with oxygen the resulting gases are rich in sulfur dioxide.[13] Noranda Mines, Ltd., continued to develop its process for recovering elemental sulfur, sulfuric acid, and iron sinter from pyrite, and a thorough study was being made to determine the best means of applying the process commercially.

Chile.—Sulfur from the Andes is relatively expensive to produce. However, during the shortage demand and prices increased, and many companies investigated the possibilities of installing new production capacity.[14]

Colombia.—Sulfur mining and processing facilities at the Purace deposit were being modernized by installation of a new plant in which sulfur would be processed by a combination of autoclaving, flotation, melting, and filtration of the sulfur.

Ecuador.—The Chemical Plants Corp. announced plans for large-scale mining operations of the sulfur mine at Tixan, Ecuador.[15]

Italy.—Production of sulfur was lower in Italy in 1951 than it was in 1950 in spite of the high worldwide demand for this product. Similarly, exports were lower. A considerable part of the decline in exports is explained by the fact that large tonnages of sulfur, accumulated in previous years, were exported in 1950, principally to Australia and France.[16] The price of Italian sulfur for export was reported to be 60,000 lire per ton in 1951.

The Italian sulfur industry was conscious of the need for improving mining and processing methods, and some progress was reported. The Economic Cooperation Administration was supplying some funds to support this work. The Italian Government appropriated 950 million lire for exploration of sulfur deposits and 9 billion lire for modernization of mines and plants. Part of the funds was earmarked for developing new mines. A description of the history and current situation of the Italian sulfur industry was published during the year.[17]

Mexico.—In 1951 the Mexican Gulf Sulphur Co. made progress in its efforts to bring San Cristobol Dome into production. This dome is located on the Isthmus of Tehuantepec. An exploration program had been carried on over a period of years. During the year a loan of $1,875,000 was arranged by the company with the Export-Import Bank to be used in developing this property. Indications were that a plant would be constructed having a capacity of 200,000 tons per year.

The Pan American Sulphur Co. continued its exploration at Jaltipan Dome on the Isthmus of Tehuantepec, and a large enough deposit had been discovered to warrant commercial development. The company was arranging for financing of the plant construction and development program.

The sulfur-recovery plant of Petroleos Mexicanos at the Poza Rica field was reported to be in operation.[18]

United Kingdom.—Britain embarked upon a program of developing additional sources of sulfur supply, both at home and abroad. New facilities to use spent oxide, gypsum, and pyrite were included in the program.[19]

PYRITES

DOMESTIC PRODUCTION

Although pyrites is in a less favorable competitive position than before World War II, output in the United States has been relatively stable in recent years and under the compulsion of the sulfur shortage increased moderately in 1951. Table 15 contains pyrites production statistics for the period 1946–51. Virtually the entire pyrites supply is consumed in producing sulfuric acid, predominantly in "captive" operations. In 1951, producing companies consumed 758,926 long tons and sold only 234,625 long tons.

Many firms gave serious consideration to converting their acid plants from elemental sulfur to a pyritic raw material, and a few applied for and received certificates of necessity under the Government sulfur-expansion program. On the other hand, the price structure was so disadvantageous to the use of pyrite that most companies were quickly discouraged, and it was clear that any large-scale conversion to pyrites would not come about until prices of crude sulfur had increased substantially as compared to pyrites.

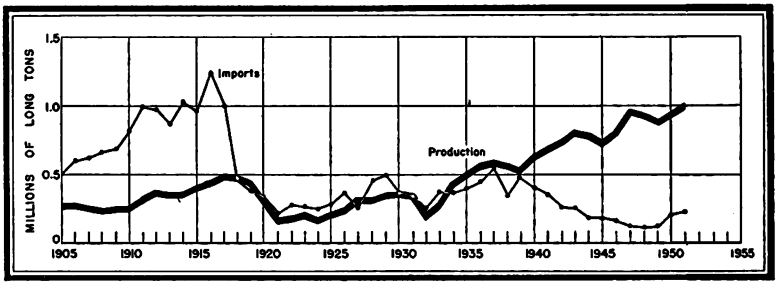

FIGURE 2.—Domestic production and imports of pyrites, 1905–51.

One prospective source of pyrites that received attention in 1951 was the high-sulfur coal of the Midwest. Large tonnages might be recovered from the waste, and thorough engineering studies were under way.[20]

TABLE 15.—Pyrites (ores and concentrates) produced in the United States, 1946–51

Year	Quantity		Value	Year	Quantity		Value
	Gross weight (long tons)	Sulfur content (percent)			Gross weight (long tons)	Sulfur content (percent)	
1946	813,372	41.5	$3,228,000	1949	888,388	42.6	$3,904,000
1947	940,652	41.7	4,070,000	1950	931,163	42.2	4,059,000
1948	928,531	41.8	3,950,000	1951	1,017,769	42.5	4,656,000

California.—The Mountain Copper Co., Ltd., more than doubled its production of pyrites from the Iron Mountain mines (formerly Hornet mine) in Shasta County, making California the second-largest producing State in 1951.

Colorado.—The Empire Zinc Division of the New Jersey Zinc Co., Eagle County, and Climax Molybdenum Co., Lake County, increased production of pyrites in Colorado in 1951.

Indiana.—Output of pyrites (coal brasses) by the Snow Hill Coal Corp. at the Talleydale mine, Vigo County, decreased somewhat in 1951.

Minnesota.—The Bureau of Mines conducted an investigation of pyrite deposits in Aitkin County, Minn., and found that a substantial deposit exists at this location.

[20] Chemical Engineering, vol. 58, No. 6, June 1951, p. 78.

Digitized by Google

Montana.—Byproduct pyrites was produced at the copper-plant operations of Anaconda Copper Mining Co., Anaconda, Deer Lodge County. Montana was the fourth-largest producing State in 1951.

New York.—Pyrites output at the Balmat mine of St. Joseph Lead Co. in St. Lawrence County, N. Y., increased slightly in 1951.

Pennsylvania.—The Bethlehem Cornwall Corp. produced pyrites at its concentrator in Lebanon County, Pa.

Tennessee.—The Tennessee Copper Co. in the Ducktown area, Polk County, continued to be the largest producer of pyrites in the United States. The pyrites concentrate was used by the company in producing sulfuric acid and sinter.

Vermont.—Vermont Copper Co. prepared to supply byproduct pyrites to the Brown Co. for use in its paper mill in New Hampshire. Approximately 9,000 tons of sulfur equivalent was to be used annually in the production of paper mill liquors. This pyrites was to be burned in a fluosolids kiln.

Virginia.—Pyrites was produced by the General Chemical Co. at the Gossan mines to supply its sulfuric acid plant at Pulaski. Virginia was the third-largest pyrites-producing State in 1951. The Freeport Sulphur Co. acquired mineral rights to a pyrite deposit in Carroll County, Va., from the Virginia Iron Coal & Coke Co. This property was not slated for early development but was available when needed.

PRICES

Transportation costs between the mine and acid plant are a very large factor in determining the prices that can be paid for pyrites at the mine. Consequently, f. o. b. mine valuations vary greatly. In 1951 producers reported f. o. b. mine evaluations ranging from $1.12 to $6.83 a long ton. The average value of all domestic output was $4.57, and the average value of the tonnage sold was $5.14. Spanish pyrites was quoted nominally at $8 per ton c. i. f. Atlantic ports by the Oil, Paint and Drug Reporter. In the early part of 1951 E&MJ Metal and Mineral Markets quoted Spanish pyrites nominally at $0.14 to $0.16 per unit, but later in the year Spanish quotations were suspended. In December domestic and Canadian pyrites per long ton was quoted nominally at $9 to $11 f. o. b. point of shipment. Average value of imports in 1951 was $2.06 per long ton.

FOREIGN TRADE

As indicated in tables 16 and 17, the only foreign pyrites that could compete in the United States market in 1951 was material produced in eastern Canada. Demand was good, even though the price trend was upward, and imports increased about 6 percent. Exports of pyrites are not separately classified in foreign-trade statistics of the United States Department of Commerce.

WORLD REVIEW

Pyrites is a more important source of sulfur in many European and Asiatic countries than it is in the United States, and therefore expansion of its output received greater attention in those countries. It was estimated that world output of pyrites increased to about 12,600,000 metric tons in 1951.

Australia.—Formation of a company in Adelaide, called Nairne Pyrites, Ltd., was announced. The company intended to acquire and explore five mineral properties at Nairne, South Australia, at which preliminary drilling indicated a large tonnage of pyrite ore.[21]

Reserves of ore in the Iron King mine were estimated at about 1,073,000 long tons. Production in 1950 was reported to have been 58,300 tons of ore, and the company was planning to increase production within 3 years to a rate of 25,000 tons per month.[22]

Digitized by Google

A new sulfuric acid plant at Port Pirie designed to produce 60,000 tons of acid per year for the fertilizer industry was to use sulfur dioxide gases from the Broken Hill Associated Smelters.[23]

Canada.—Arnora Gold Mines concluded an agreement with Freeport Sulphur Co. for the sale of a group of five claims in Joannes Township, Northwestern Quebec.[24] Exploratory drilling of a pyrite deposit was being conducted by this company in Languedoc Township, Quebec, about 30 miles north of Noranda mines.[25]

Stratford Metals, Ltd., was preparing to drill for pyrites in Stratford Township, Wolfe County, Quebec. The deposit is approximately 7 miles from St. Gerard on the Quebec Central Railway.[26]

China.—The problems involved in the development of sulfuric acid production capacity based on local pyrites in the Orient were described in a recent article.[27]

Cyprus.—Ore reserves were estimated at 5,741,000 tons at the Lumni property of Cyprus Copper & Sulphur Co., Ltd. Of this total about 1,000,000 tons was said to represent oxidized ore which overlies the main sulfide ore body.[28]

Finland.—Milling practice at the Outokumpu mill, where pyrite is recovered as a byproduct of zinc and copper operations, was described in a trade article.[29]

Greece.—Production of pyrite in Greece increased sharply in 1951. Of the total production (somewhat over 180,000 tons) 150,167 tons valued at $1,431,028 was exported.[30]

Norway.—It was reported that the Gravdal mine in Western Norway, which had been idle since the last war was to be rehabilitated and put back into production. Projected output was to be 15,000 tons a year.[31]

India.—As part of the Point IV Program a survey of sulfur resources in India was made by F. E. Hilburn, a representative of the United States Government. His report (unpublished) indicated that the most promising source of sulfur is the smelter of the Indian Copper Corp. at Moubhandar in southeastern Bihar. Thorough investigation of the pyrite resources of the country also was recommended. Among the deposits mentioned are the following: Amjor in northwestern Bihar, Karwar in southern Bombay, Chitaldrug in the State of Mysore, the Pandalur-Devale-Madghani region in western Madras, and Simla in the Keonthral State. The Amjor deposit appears to be the most promising at present. This deposit is about 20 miles south of Dehri-on-Sohne in western Bihar. A study of the possible utilization of gypsum for the production of sulfuric acid also was

recommended. The gypsums available have certain disadvantages, such as high silica content and remoteness of location from the consuming areas.

The Sindhri fertilizer plant was to use gypsum from the Bikaner deposits in the Rajasthan desert in western India for the production of ammonium sulfate. Utilization of gypsum in India for the production of either fertilizer or sulfuric acid is hampered by the distance between the deposits and the consuming areas.

Portugal.—In 1951 the pyrite industry fared very well in Portugal. Demand was firm, and both prices and production increased. Production of elemental sulfur by the Orkla process totaled 14,124 tons in 1951, and the plant was operated at full capacity. A program of modernization and expansion of pyrites production was under way at the Louzal and Aljustrel mines during the year. The Mina de San Domingos, operated at about one-half of capacity, but proved ore reserves were not adequate to warrant a higher production rate. Exploration programs were being conducted by all three companies.[32]

Spain.—A number of companies indicated interest in developing additional pyrites-production capacity in Spain and optimistic statements appeared in the press regarding the anticipated increase.[33] The mining industry encountered a number of problems that made expansion of pyrite capacity difficult; but overall output increased considerably during the year, even though it did not ultimately attain the anticipated rates of production.

Talc and Pyrophyllite

By Bertrand L. Johnson and F. P. Uswald

GENERAL SUMMARY

MARKED increases over 1950 to record highs distinguished the 1951 mine production of talc, pyrophyllite, and ground soapstone and the quantity and value of these commodities sold or used. Total imports were less in quantity, but higher in value, in 1951 than in 1950. Exports of crude and ground talc, steatite, soapstone, and pyrophyllite were greater in both quantity and value in 1951 than in the preceding year. Exports of talcum powders also rose considerably in total value in 1951.

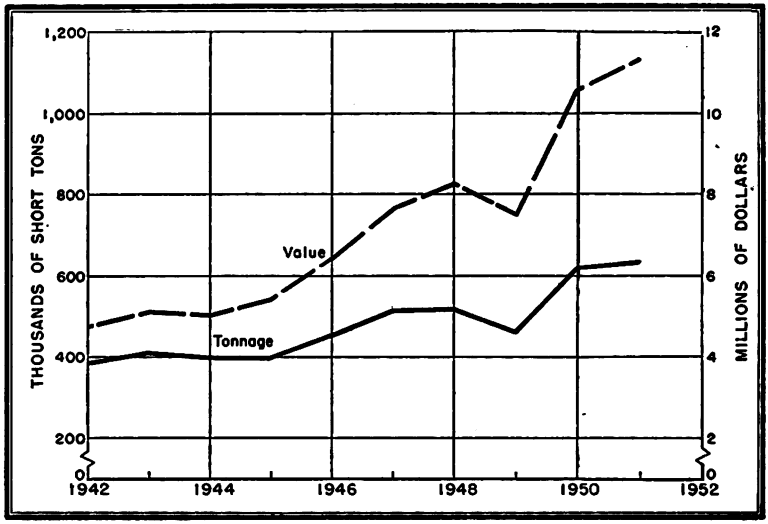

FIGURE 1—Sales of domestic talc, pyrophyllite, and ground soapstone, 1942–51.

[1] Figure not available.
[2] Includes some crushed material.
[3] Exclusive of "Manufactures, n. s. p. f. (not specially provided for), except toilet preparations," as follows: 1950: $7,574; 1951: $2,178. Quantities not available.
[4] Includes "Manufactures, n. e. s."
[5] Revised figure.

On June 20, 1951, the National Production Authority published a List of Basic Materials and Alternates in which Indian block talc was stated to be in such short supply that alternates should be used wherever possible; ground talc (including steatite) was in tight supply, so expanded use should be avoided by industry; and pyrophyllite was in fair supply and therefore should be used as a substitute for block and ground talc wherever possible.

Two reports on California talc deposits appeared in 1951.[1]

PRODUCTION AND SALES

Both the quantity and value of domestic talc, pyrophyllite, and ground soapstone sold in 1951 (636,068 short tons valued at $11,322,830) were higher than in 1950 and constituted new records. The mine production of pyrophyllite and the quantity and value of that mineral sold were at new highs.

REVIEW BY STATES

In 1951 the talc alone sold by producers in New York still exceeded both in tonnage and value, by a large margin, the combined talc, pyrophyllite, and ground soapstone sold by producers in any other State; tonnage sales in New York, however, fell sharply. California was second and North Carolina third. Sales in California, Georgia, Maryland and Virginia, and Vermont were higher in 1951 than in 1950. Sales of pyrophyllite increased slightly in 1951 over 1950.

[1] Includes Montana, Texas, and Washington.

CONSUMPTION AND USES

Six industries—ceramic, paint, insecticide, rubber, roofing, and paper—purchased 86 percent of the domestically produced talc, pyrophyllite, and ground soapstone sold in 1951, according to reports from the producers. There were substantial increases over 1950 in sales to the ceramic, insecticide, and roofing industries. A noteworthy change has occurred among the leading consuming industries since 1949. The ceramic industry became an increasingly important consumer, taking 27 percent of total sales compared with 24 percent in 1950, and the paint industry, which took 23 percent in 1950, fell to only 19 percent in 1951.

TABLE 5.—Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1949–51, by uses [1]

Use	1949		1950		1951

PRICES

The trend in the average value per ton of domestic talc, pyrophyllite, and ground soapstone sold has been steadily upward in recent years. It rose in 1951 to $17.80 per short ton from $17.11 in 1950.

The prices of talc, pyrophyllite, and ground soapstone were included under the general price freeze order (General Ceiling Price Regulation—GCPR—January 26, 1951), in which prices were set at the highest level reached in the base period between December 19, 1950, and January 25, 1951. The following table shows the prices of ground talc and pyrophyllite at the beginning of 1950 and 1951 and at the end of the latter year, as quoted by the Oil, Paint, and Drug Reporter. No change is shown in the prices for ground talc during 1951, but pyrophyllite prices rose after the early price freeze, so that, at the end of the year, they stood at a considerably higher level than during the base period.

TABLE 6.—Prices quoted on talc and pyrophyllite, carlots, 1950–51, per short ton

[1] Off color.
[2] Not quoted.
[3] In paper bags, $3 to $3.50 per ton extra.

FOREIGN TRADE [2]

Imports.—The total quantity of unmanufactured talc, steatite or soapstone, and French chalk imported for consumption in the United States decreased 11 percent (2,747 short tons) in 1951 from 1950; and dropped to 20,640 short tons. The value of the imports, however, rose slightly to $694,066. The quantity of "crude and unground" material imported fell from 177 tons to 109, but the value doubled. There were decreases in both quantity and value of the imports of other classifications of the unmanufactured material. As usual, the greater part of

[1] Less than 0.5 ton.

the unmanufactured imports was "ground, washed, powdered or pulverized, except toilet preparations," of which 20,404 tons valued at $631,707 was imported in 1951. Most of the ground material came from Italy, with Canada in second place and France third. Imports of the manufactured material (n. s. p. f., except toilet preparations) declined in value to only $2,178. The manufactures came principally from China.

Exports.—Both the quantity and value of "talc, soapstone, and pyrophyllite" exported from the United States in 1951 reached new highs. The quantity of crude and ground exports increased 2,310 short tons to 22,903 tons and the value rose $84,465, a greater percentage increase, to the new record of $645,217. Exports of "manufactures, n. e. s.," while still relatively small, more than doubled. The value of exports of "powders-talcum (in packages), face and compact" increased nearly a quarter of a million dollars above that of 1950 to $1.5 million.

[1] In addition to countries listed, talc or pyrophyllite is reported for Afghanistan, China, Portugal, and U. S. S. R., but data on production are not available; estimates have been included in total.
[2] Data not available; estimate by chapter author included in total.
[3] Revised figure.
[4] American zone only.
[5] Bizonal area.
[6] Includes steatite as follows: 1946: 19,541; 1947: 20,835; 1948: 18,627; 1949: 20,880; 1950: 13,702; 1951: 22,628.
[7] Talc, pyrophyllite, pinite, and ground soapstone sold by producers. (No pinite sold by producers in 1949, 1950 or 1951.)

Canada.—According to official preliminary estimates [3] Canada produced in 1951 13,480 short tons of talc (value $164,550), 15,600 short tons of soapstone (value $162,900), and 107 tons (value $535) not differentiated as between talc and soapstone. Imports of talc and soapstone in 1951 were given as 9,283 tons (value $306,277), and exports of talc, 3,743 tons (value $48,857).

The Canadian talc and soapstone industry in 1950 was described as follows: [4]

Producers' shipments of talc and soapstone during 1950 amounted to 32,604 tons valued at $364,995 compared with 26,922 tons valued at $320,793 in 1949. Production in Ontario was mostly high-grade milled talc but output from workings in Quebec included crayons, blocks and ground soapstone. In British Columbia test shipments of talc and pyrophyllite were made and although the ground material had not been sold at the year-end, nominal values were assigned for statistical purposes.

The industry employed 58 persons and distributed $116,547 in wages and salaries during the year. Fuel cost $5,460 and 1,519,975 k. w. h. of electricity were purchased for $22,090.

Imports of talc and soapstone totalled 8,974 tons worth $288,020. Canadian exports of talc in 1950 amounted to 4,467 tons valued at $57,621.

Tin

By Abbott Renick and John B. Umhau

GENERAL SUMMARY

THE YEAR 1951 was an eventful one in the international tin trade, featured by soaring prices and the decline of the tin market. All new purchases of tin for the National Strategic Stockpile were suspended; private importation of tin was stopped, and the Reconstruction Finance Corporation was made the sole importer of tin; the Preparedness Subcommittee of the Senate Armed Services Committee published a comprehensive report on the tin situation; the National Production Authority placed tin under allocation control; and the RFC disputed with Bolivia what was considered to be a reasonable price for tin.

In the hope of arresting the unprecedented rising prices and re-establishing the normal market for tin, the United States Government invited major tin-producing countries to convene with its representatives in Washington. The resulting conferences, held March 14–28, concluded without reaching any agreement. Subsequently, a United States mission examined tin mines, smelters, and tin marketing in the Federation of Malaya and Singapore. The International Tin Study Group met again during 1951.

The Preparedness Subcommittee of the Senate Committee on Armed Services conducted a comprehensive investigation on tin, culminating in a report issued on March 5, 1951.[1] Among other measures the report recommended that tin purchasing be centralized in a single Government department and that stockpile purchasing be suspended until prices decreased to a reasonable level. The committee concluded that in case of war enough tin stocks were on hand to satisfy United States requirements, provided that stringent control and conservation measures were put into effect. A major recommendation of the subcommittee report called for an international conference of representatives of the tin producing and consuming countries to stimulate production, allocate tin supplies, and reduce the price. The committee recommended that the National Production Authority institute more stringent tin conservation and allocation measures. An offer of technical assistance to tin producers by the United States Government on a cooperative basis was also recommended.

On January 12, 1951, the RFC was requested to undertake the function of acquiring and disposing of tin-bearing materials (metals, ores, concentrates, etc.) in connection with the defense program. In accordance with the Defense Production Act of 1950 and Executive Orders 10161 and 10200, the Administrator of the General Services Administration, on March 5, 1951, delegated to the RFC the authority to purchase and make commitments to purchase tin metal, tin ores

Digitized by Google

and concentrates, and tin contained in slags, flue dust, and drosses for Government use or for resale.

On March 7 the General Services Administration suspended all new purchases of tin for the National Strategic Stockpile, and announced that purchases by the Government for industrial uses would be held to a minimum.

NPA Order M-8, effective March 12, 1951, designated RFC, acting for and in behalf of General Services Administration, as the sole importer of pig tin. The same order placed all domestic users of pig tin, with limited exceptions, under allocation by NPA, beginning May 1, 1951.

World mine production of tin totaled 169,100 long tons in 1951, virtually unchanged from the 169,000 produced in 1950. World smelter production decreased 7,400 tons (4 percent), principally because of decreases of 4 percent in the output in both Malaya and the United States. World consumption decreased 8 percent.

The United States mine output of tin continued to be negligible, although Government assistance, afforded under the Defense Production Act of 1950, initiated the equipping of a tin mine in Alaska. A small production of tin resulted as a byproduct from the mining of molybdenite in Colorado.

Consumption of tin in 1951 in the United States, which was under Government control through the year, decreased 16 percent under 1950; consumption of primary tin decreased 20 percent and of secondary tin 6 percent. Domestic smelter output, nearly all from the Government-owned smelter at Texas City, Tex., decreased 1,266 long tons (4 percent) from 1950. Secondary tin production was 3 percent less than in 1950.

Metal imports decreased 66 percent, representing 48 percent of the total tin imported. Receipts of concentrates, in terms of metal, were 14 percent higher than in 1950. The increase was due chiefly to larger receipts from Indonesia and Thailand. Imports of tin in concentrate from Bolivia decreased 9 percent.

The total stocks of tin in the United States and in transit as of December 31, 1951, were 40,448 long tons, exclusive of the National Stockpile and metal afloat to the United States. As a reserve for civilian deficiency, the RFC on December 31, 1951, held 6,753 long tons of pig tin. On December 31, tin concentrates and other tin-bearing materials held by the RFC contained an estimated total tin content of 11,878 long tons. As of December 31, tin stocks held by industry and in transit to consuming plants were 21,817 long tons.

Tin prices in 1951 fluctuated violently. The price of tin in New York, which had risen from 76.4 cents per pound just before the outbreak of war in Korea to $1.51 at the beginning of 1951, reached $1.83 on January 25. On February 14 the Singapore price reached $1.93, equivalent to $1.97 in New York. As a result of suspension of all new purchases for the National Stockpile, together with the announcement that purchases by the Government for industrial uses would be held to a minimum, the price of tin fell to $1.34 per pound on March 9. A price of $1.03 was reached on August 1, 1951, and maintained to December 31, 1951. The annual average for 1951 was $1.28 per pound, the highest on record.

[3] Revised figure.

GOVERNMENT REGULATIONS

Tin controls were tightened in 1951 to assure supplies for the rearmament program and to provide for equitable distribution of the remaining supply and encourage conservation. National Production Authority Order M–8, first issued in 1950, was further amended to limit monthly use and place tin supplies under allocation in 1951. Uses of tin not expressly set forth in schedules in M–8 were prohibited. During January 1951 consumption of pig tin was limited to 100 percent of the monthly average usage during the 6-month-base period ended June 30, 1950. During February and March industry was restricted to 80 percent of base-period use; during April, May, and June the rate was increased to 95 percent for tin platers and 90 percent for all other users. On March 12, 1951, the RFC was designated the sole importer of tin in the country to bring about more orderly arrangements for acquiring tin needed in the United States. Commencing May 1, 1951, pig tin was placed under allocation by prohibiting, subject to limited exceptions, any deliveries not covered by allocation authorizations to be issued monthly by the NPA. During the last half of 1951 all users were limited to 90 percent of base period use. Previous limitation rates allowed extra quantities for producing implements of war, but after July 1 all uses were made subject to the 90-percent limit. Limitations on pig-tin inventories were 120 day's supply for tin-plate manufacturers and 60 days for all other users.

The use of pig tin for making tin plate and terneplate was limited by M–8, which also permitted the use of tin for tin plate and terneplate in accordance with NPA Order M–24. M–24 controlled the uses of tin plate and terneplate (for cans M–25 and for closures M–26), the permitted materials in these uses, and the maximum permitted coatings of tin or terne metal. Effective July 1, 1951, tin plate and terneplate became subject to allotments under the Controlled Materials Plan (CMP). The use of tin in the manufacture of collapsible tubes was limited by Order M–27, the percentage varying with products to be packaged in the tubes.

DOMESTIC PRODUCTION

MINE OUTPUT

Domestic mine production of tin was again insignificant. Only 88 long tons of tin was produced in 1951 compared with 94 tons in 1950. Alaska again supplied virtually all the output. Mining in Alaska in 1951 was confined mainly to placer deposits of the Northern Tin Co., Inc., on Buck Creek and the United States Tin Corp. at Lost River in the Port Clarence district in the western part of Seward Peninsula. No lode tin was mined during 1951 from any Alaska deposits.

Small quantities of byproduct tin were produced in Colorado by the Climax Molybdenum Corp. and in North Carolina by the Foote Mineral Co.

Under the Defense Production Act of 1950, a financial assistance contract in the form of a 90-percent Government guaranty operating loan was negotiated with the United States Tin Corp. A mill building was erected and the installation of equipment was started at the old Lost River tin-tungsten lode mine in Alaska. The contract was one of the first of this type approved in the minerals field. On August 6, 1951, the Defense Minerals Administration released a list of approved minerals exploration projects which included two tin investigations, one by the Zenda Gold Mining Co., Seward Peninsula, Alaska, and the other by Keenan Properties, Lawrence County, S. Dak., with Government participation indicated at $54,000 and $90,000, respectively.

TABLE 2.—Mine production of tin (content) in the United States, 1942–46 (average) and 1947–51, by States, in long tons

Year	Alaska	South Dakota	Colorado	Other States	Total	
					Long tons	Value
1942–46 (average)	1.0	0.5	----	2.0	3.5	$4,060
1947	1.3	----	----	----	1.3	2,200
1948	[1] 4.7	(1)	----	----	4.7	10,380
1949	51.6	----	16.8	----	68.4	152,210
1950	79.5	----	14.6	----	94.1	201,446
1951	68.6	----	18.8	.6	88.0	252,920

[1] A very small quantity from South Dakota is included with Alaska.

SMELTER OUTPUT

Smelters in the United States produced 31,852 long tons of tin in 1951 compared with 33,118 tons in 1950. Production was virtually entirely that of the Government-owned smelter at Texas City. This smelter (Longhorn smelter) produced 30,934 long tons of pig tin—all 3-Star—(including 15 of secondary from drosses) in 1951 and 32,136 tons (including 44 of secondary from drosses) in 1950. Production of pig tin by the smelter in November and December 1951, was the lowest since August 1943. In addition, the production of Copan alloy (containing 84 percent tin) amounted to 700 long tons in 1951 and 940 tons in 1950.

The Longhorn smelter treated concentrates mainly from Bolivia, Indonesia, Thailand, and the Belgian Congo in 1951. The average grades of alluvial, Bolivian, and miscellaneous concentrates treated

Digitized by Google

during the 15 months ended June 30, 1951, and for the 6 months ended December 31, 1951, were as follows:

Average percent tin content

	15 months to June 30, 1951	*6 months ended Dec. 31, 1951*
Alluvial	73. 58	73. 17
Bolivian	34. 54	34. 13
Miscellaneous	56. 33	53. 48
Average	47. 09	48. 64

The average analysis of the concentrates used in 1942–49 was: [1a]

	Percent of concentrates	
	Bolivian	*Alluvial*
Sn	38. 0	73. 5
S	6. 0	-----
Pb	. 5	. 4
Sb	. 4	. 02
As	. 4	. 02
Bi	. 04	. 01
Cu	. 2	. 01
Zn	. 6	. 06
Fe	16. 0	3. 0
SiO_2	13. 0	2. 0

Of the total tin produced at the Longhorn smelter in 1951, 98 percent was 3-Star and 2 percent was Copan alloy. The smelter upgraded, remelted, or recast 1,528 tons in 1951. Of this 902 tons were recast into 3-Star from previously produced 3-Star (100 tons) and 2-Star (802 tons); and 626 tons of Copan to Copan. The Longhorn smelter continued to be operated on a cost-plus-fixed-fee arrangement by Tin Processing Corp. (a Delaware corporation and a subsidiary of N. V. Billiton Maatschappij). The contract with the firm was extended to June 30, 1952.

The Vulcan Detinning Co. recovered tin from low-grade concentrates in early 1951 but discontinued doing so during the summer, and the plant built for the purpose was placed in standby condition. In 1951, the RFC purchased 190 long tons of tin recovered in the United States by the Vulcan Detinning Co. from concentrates of foreign origin. Thereafter the Longhorn tin smelter became the only one operating in this country.

RFC assets of property, plant, and equipment under the tin program, but excluding stocks of tin metal, ores, and materials in process, were valued at $11,631,015 as of June 30, 1950, and had been increased to $12,439,928 by June 30, 1951. Direct operating costs before depreciation or byproduct credits totaled $5,872,288 in the calendar year 1951 ($5,667,028 in 1950). Operating cost per long ton of tin bullion produced from primary ores increased from $173 for the fiscal year ended June 30, 1951, to $220 in the last 6 months of 1951, because of curtailed production necessitated by the lack of ore. Although the total payroll was reduced from 914 on June 30 to 793 on December 31, 1951, overhead and maintenance costs could not be reduced, and the efficiency of operations in general suffered from the low rate of production. Tungsten-leaching operations and the production of

Digitized by Google

synthetic scheelite were suspended at the end of September, when all Bolivian ores containing enough tungsten to cause furnace trouble by hearth accretions had been treated.

TABLE 3.—Longhorn tin-smelter production, 1942–51, by months, in long tons

[1] Includes 238 tons of secondary from drosses.
[2] Includes 44 tons of secondary from drosses, but excludes tin content of ores (621 long tons) used direct to make alloys. Also exclusive of tin recovered from remelts.
[3] Includes 15 tons of secondary from drosses, but excludes tin content of ores (592 long tons) used direct to make alloys; also exclusive of tin recovered from remelts.

SECONDARY TIN

Recovery of secondary tin decreased 3 percent in 1951 compared with 1950. The value, however, was 30 percent greater than in 1950. Most of the tin recovered was contained in copper-, tin- and lead-base alloys. Only 3,300 long tons was recovered in the form of metallic tin, mostly by the detinning plants.

Tin recovered in copper-base alloys from scrap (accounting for 58 percent of the total recovered in all products in 1951) increased nearly 30 percent, while recoveries in white-metal alloys decreased 34 percent.

Detinning plants treated 481,443 long tons of tin plate clippings in 1951—the largest tonnage on record, exceeding the previous peak reached in 1950 by nearly 3 percent. In addition, old cans processed increased 32 percent to 22,131 long tons in 1951, compared with 16,818 tons in 1950; this was a small figure, however, compared with the record use of 175,870 tons in 1943. In total, 3,565 long tons of tin was recovered from this material. Tin recovered from tin-plate clippings in 1951 was 3,416 tons, 9 percent less than 1950, while that from old cans, 149 tons (mostly in the form of pig tin), increased 38 percent.

TABLE 4.—Secondary tin recovered in the United States, 1942–46 (average), and 1947–51, in long tons

Year	Tin recovered at detinning plants			Tin recovered from all sources			
	As metal	In chemicals	Total	As metal	In alloys and chemicals	Total	
						Long tons	Value
1942–46 (average)	3,516	288	3,804	3,920	26,660	30,580	$35,880,813

CONSUMPTION

APPARENT CONSUMPTION

In 1951 the apparent consumption of primary tin, computed by adding domestic smelter production to net imports, amounted to only about half of that in 1950. As changes in consumer, dealer, and Government stocks are not taken into account, apparent consumption may vary greatly from actual consumption as measured in finished products. Table 5 gives the data for 1942–46 (annual average) and 1947–51. A comparable series for 1910–38 was published in Minerals Yearbook, 1939 (p. 680), and for 1939–48 in Minerals Yearbook, 1948 (p. 1212).

TABLE 5.—Apparent consumption of primary tin,[1] 1942–46 (average) and 1947–51, in long tons

Year	Long tons	Year	Long tons
1942–46 (average)	44,752	1949	95,904
1947	57,771	1950	115,156
1948	85,808	1951	58,123

[1] Includes some secondary metallic tin in imports whose quantity cannot be separately determined.

CONSUMPTION BY USES

Total domestic consumption of tin was 16 percent less in 1951 than in 1950. The use of primary tin decreased 20 percent and secondary 6 percent. The tin content of manufactured products was 88,169 long tons in 1951 (56,884 of primary and 31,285 of secondary) compared with 104,464 tons in 1950 (71,191 of primary and 33,273 of secondary). The tin plate and terneplate industry decreased its use of tin 14 percent, while the total quantity used by all other industries decreased 17 percent.

Five items—tin plate and terneplate, bronze and brass, solder, babbitt, and tinning—accounted for most of the total tin consumed in 1950 and 1951. Tin plate and terneplate took 35 percent (same in 1950), bronze and brass 25 percent (20 in 1950), solder 22 percent (26 percent in 1950), babbitt 7 percent, and tinning 3 percent. Uses of primary tin decreased in 1951 as follows: Tin plate 14 percent, solder and babbitt 29 percent, tinning 13 percent, collapsible tubes and foil 42 percent, pipe and tubing 65 percent, type metal 35 percent, and chemicals and oxide 57 percent. Bronze and brass was the only item that increased (16 percent) its use of primary tin, resuming its former wartime importance as the second largest user of tin. Tonnagewise, conservation was mainly effected in the use of primary tin for making solder (5,277 tons less), tin plate (4,858 tons less), collapsible tubes and foil (606 tons less), babbitt (1,008 tons less), miscellaneous alloys (699 tons less), and chemicals and tin oxide (495 tons less).

Tin mills operated at a lower rate in 1951 and produced 4 percent less tin plate than in the peak year 1950. In 1951 over half of the primary tin consumed was for making tin plate. About 61 percent of the tin used to make tin plate (excluding waste-waste, etc.) in 1951 was for hot-dipped and 39 percent for electrolytic. Hot-dipped tin plate production, however, accounted for only 35 percent and electrolytic 65 percent of the total output (excluding waste-waste, etc.) in 1951.

Digitized by Google

Electrolytic tin plate requires considerably less tin per unit of product than hot-dipped. Electrolytic lines established a new annual record in 1951 and produced 5 percent more tin plate than in 1950. Hot-dipped tin plate production declined 16 percent and was the smallest tonnage recorded since 1932. Terneplate production required 19 percent less tin in 1951 than in 1950. Short-terne output decreased 14 percent, whereas long ternes increased 3 percent.

Net industrial receipts of tin in 1951 were 81,139 long tons (30 percent less than in 1950), of which 60 percent consisted of primary pig tin. Receipts of primary tin decreased 40 percent and secondary or scrap 7 percent. Straits tin supplied 68 percent of primary receipts

TABLE 6.—Consumption of primary and secondary tin in the United States, 1942–46 (average) and 1947–51, in long tons

reported by plants in 1950 and only 25 percent in 1951, as virtually no tin was shipped from Malaya to the United States after March. The principal brand acquired in 1951 was Longhorn produced by the Texas City smelter, which has supplied industry almost half of its pig tin since 1942. Straits, the product of the large smelters in Malaya, was the principal brand used in the United States before the Second World War.

STOCKS

Stocks of pig tin and tin in ore were 14 percent lower at the end of 1951 than at the beginning of the year. Tin in process, in scrap, and as secondary tin totaled about 10,720 tons (11,150 at beginning of year). Industrial stocks of primary tin were reduced 50 percent, with 56 percent of the total plant stock held by tin platers. Industrial plant stocks of pig tin at the end of 1951 were the lowest since the end of 1935. RFC stocks of tin metal were 18,618 tons comprising undelivered balances of industrial sales contracts, including 390 tons at beginning of the year compared with 6,753 at the year's

Digitized by Google

close; stocks of concentrates contained 15,068 tons of tin at the beginning of the year and 10,771 at the close; ores afloat or in foreign ports at the beginning of 1951 contained 5,606 tons and at the end of the year 1,107 tons.

TABLE 9.—Stocks of virgin pig tin in the United States, Dec. 31, 1946–51, in long tons [1]

	1946	1947	1948	1949	1950	1951
At consumers' plants	14,532	13,677	14,349	13,771	20,576	10,043

[1] Excludes Government purchases delivered for stockpiling or at Texas City smelter. Also excludes tin in process and secondary pig tin.

PRICES

The average price of Straits tin in New York in 1951 was $1.28308 a pound, the highest on record. The peak monthly average was $1.8268 in February. At the beginning of the year the quotation stood at $1.50 a pound, having dropped 1 cent over the New Year holidays. However, unfavorable Korean news and the general feeling of uncertainty brought on a steady advance until January 25, when the highest price recorded in the regular New York market reached $1.84 a pound. On January 26, 1951, the Office of Price Stabilization issued a General Ceiling Price Regulation which established ceilings based upon prices that had been in effect from December 19, 1950, to January 25, 1951, inclusive.

On February 1, sales for spot and prompt delivery in the New York open market were reported at $1.825 a pound, establishing the market. Ceiling prices were maintained at $1.835 a pound under GCPR. On February 13 the price was advanced to $1.83 a pound. This price advance added confusion to the price structure on a world marketing basis. Following the GSA announcement on March 6 halting all tin purchases for the National Stockpile, New York prices dropped sharply.

The Sixth Report of the Preparedness Subcommittee of the Committee on Armed Services, United States Senate, Document 13, Tin 1951, dated February 12 and released March 5, 1951, criticized tin production and marketing policies. The committee recommended that the United States halt purchases of tin until prices returned to a lower level, that one Government agency become sole purchaser for account of American consumers, and that NPA impose much more stringent tin-conservation measures than were in effect.

On March 6 the General Services Administration announced that all new purchases of tin for the National Stockpile would be suspended immediately; purchase of tin by the Government for industrial use would be held to the barest minimum, and authority was redelegated to the RFC for the purchase and resale of tin. On March 12 the National Production Authority designated RFC as the sole importer of tin in the country. (On November 8 the Defense Production Administration announced that further stockpiling of tin was to

Digitized by Google

be discontinued at once and all tin purchased would be made available for industrial consumption, pursuant to allocations. The announcement said the step was taken because of the inability to obtain foreign tin at "a fair and reasonable price.")

From March 14 to 28 an International Tin Conference in Washington considered a long-term stabilization market program on pricing and distribution. Delegates from the United States, United Kingdom, British Colonial Territories, Belgium, the Netherlands, and Indonesia participated. The conference adjourned without reaching an agreement.

On March 12, when RFC became sole importer, the price was nominal at $1.34 a pound, the last open-market quotation. The RFC price on March 13 was $1.34. Thereafter, in line with its established policy of bringing about a more reasonable price, 12 changes were made, mostly below the going world price established in Singapore. By August 1 the RFC price had been established at $1.03 per pound, at which level it remained for the rest of 1951. (The RFC price was $1.03 from June 1, 1948 to September 28, 1949).

"Tin-metal, ore concentrates, powder, and scrap alloys" were excepted from Ceiling Price Regulation 31—Imports, which became effective May 9, 1951, because it was covered by a United States Government purchase program.

TABLE 10.—Monthly price of Straits tin for prompt delivery in New York, 1950–51, in cents per pound [1]

[1] Compiled from quotations published in the American Metal Market.
[2] Highest price recorded in regular market was $1.84 on Jan. 25, 1951, with a reaction to $1.83 at close o market on that day.
[3] RFC became sole procurer of tin in the United States on Mar. 12, 1951.
[4] 1 small lot reported sold in the forenoon of Nov. 8, at $1.6350 with reaction at the close to $1.55.

London and Singapore were the only free tin markets in 1951. The average London price for standard tin was £1,079.6 a long ton in 1951. The monthly average price fluctuated from the high of £1,470.3 in February to the low of £880.7 in August 1951, as it slowly followed the United States price downward. When the market year opened on January 2, 1951, this price was £1,130. By January 24 it had reached £1,235. The price-freezing order of January encouraged a sharp upward movement, and on February 14 tin changed hands at the record price of £1,615 per ton ($2.01875 per pound, equivalent New York price). The price thereafter gradually declined to £805 on August 2 (the lowest of the year) from which it recovered, despite lack of buying by the United States, to £1,030 in October. Monthly

Digitized by Google

prices averaged £966.2 (equivalent of $1.2078 per pound) during the last 4 months of 1951. At the close of 1951, the price was £905. English tin was under a voluntary embargo for export by members of the London Metal Exchange.

The Singapore market price for Straits ex works averaged £1,040.3 for 1951. The monthly average price reached the all-time peak of £1,451.6 in February. The quotation on February 14 was £1,547.5 ($1.93 a pound), the highest recorded. On March 13 (the day after RFC took over) the price was £1,116 (or the New York equivalent of $1.44 a pound). Between June 8 and August 1 Singapore prices were more or less the equivalent of RFC prices. The lowest monthly Singapore average was £830.3 ($1.0378 per pound U. S.) for July. The lowest price for the year was £790⅞ on August 7, following the Bank holiday observance, with sales at good volume. Average prices increased in September and October but settled down in November and December. On December 31, 1951, the price was £866.5.

FOREIGN TRADE[2]

Imports of tin concentrates and exports of tin plate were the principal items of foreign trade of the United States during the year. Pig tin, which had dominated the import field before World War II and since 1947, gave way both in quantity and value to tin concentrates. Of less importance has been foreign trade in tin-plate and terneplate scrap, circles, strips, waste-waste, miscellaneous tin and manufactures, and compounds. Imports of tin-plate scrap were 51,571 long tons in 1951 against 42,394 in 1950. In 1951 exports of tin-plate scrap were 810 long tons (562 in 1950), mostly to Mexico and Japan. Exports of tin cans were 33,171 long tons in 1951 compared with 28,946 tons in 1950.

Imports of metallic tin in 1951 were 66 percent less than in 1950, mainly because no Malayan tin was shipped to the United States after March. Of the total, 45 percent came from the Netherlands, 25 percent from Malaya, 23 percent from Belgium and the Belgian Congo, and the remainder from other sources. Receipts of ore, in terms of metal, were 14 percent greater than in 1950, principally due to substantial gain in imports from Indonesia. Bolivia was the main source of tin ore, accounting for 44 percent of the total, but furnished only 13,082 tons in 1951 (9 percent less than in 1950). Bolivia was the source of two-thirds of the tin in ores imported from 1941 to 1951, inclusive. Imports from Bolivia in 1951 were the smallest for any year since the tin smelter was put into operation at Texas City, Tex., in 1942.

Exports of metallic tin in 1951 were 1,513 long tons (the highest since 1943), with Canada as the destination of nearly 90 percent. Tin exports were under export license control.

The major tin-export item of the United States, as usual, was tin-plate (including terneplate), which increased 13 percent in 1951. Gains were made in the export markets of Latin America (most Argentina and Brazil), Australia-New Zealand, and Asia (mostly

India). Exports to European countries decreased 6 percent. Shipments to Africa decreased about 3 percent despite the increase in tonnage to the Union of South Africa.

Exports of hot-dipped tin plate totaled 270,327 long tons, valued at $64,009,163 in 1951. Principal countries of destination were Australia (41,857 tons), Argentina (32,527 tons), Brazil (30,521 tons), Netherlands (28,989 tons) Union of South Africa (17,157 tons), and Italy (15,871 tons). Exports of electrolytic tin plate, totaling 209,762 long tons, valued at $45,781,174, were shipped to 60 countries, the leading ones being Brazil, Union of South Africa, Netherlands, Australia, and Argentina. Most of the terneplate exported went to Canada in 1951.

According to the American Iron and Steel Institute, producers in 1951 shipped for export 581,703 short tons (490,230 in 1950) of tin plate, of which 346,231 tons (392,651) was hot-dip and 235,472 (97,579) electrolytic.

TECHNOLOGY

The Tin Research Institute [3] opened its new laboratories near London on May 31, 1951. Advantage was taken of the new laboratory extensions to begin investigations into the testing of alloys in the form of actual bearings and the casting of bronze in the form of long bars. Chief interest was centered on pilot-stage work on electro-

[3] Information concerning the institute's work and publications can be obtained in the United States from Tin Research Institute, Inc., 429 West 6th Ave., Columbus, Ohio.

Digitized by Google

deposited tin-alloy coatings. The institute released for publication several technical reports on varied subjects relating to tin and its industrial application. These releases included a paper summarizing the electrode position and corrosion resistance of a new tin-nickel alloy. The coating consists of 2 parts of tin and 1 part of nickel. It has a beautiful metallic luster with a faint rose-pink color, is hard, is as untarnishable as chromium, and can be deposited bright in one operation.

Rapid tinning of small aluminum and aluminum alloys was reported possible by use of an ultrasonic soldering bath. The ultrasonic transducer, which forms the basis of the soldering bath, makes use of the phenomenon known as magnetostriction, which is connected with the small dimensional changes that occur in ferromagnetic materials when they are placed in a magnetic field.[4]

A new tin-plate coating-thickness gage was put into operation. Adaptable to measuring tin-coating thicknesses for different kinds of cans, this new gage takes advantage of two instruments, the X-ray and the Geiger counter. It is capable of measuring thicknesses with a margin of error less than six ten-millionths of an inch. Completion of a new continuous annealing line at the Gary sheet and tin mill was announced. With 3,000 feet of sheet or strip in continuous process, this ingenious line is capable of giving a "universal temper" to about 136,000 net tons of material each year for can manufacturers.[5]

A high-temperature calorimeter designed for use up to 1,500° K. was described and the theory of operation presented. This calorimeter was used in 1951 to measure the heats of formation of sodium-tin alloys.[6]

"Improved Aluminum Bearings (Aluminum-Tin and Aluminum-Tin-Copper Alloys)" was the title of a paper. These alloys were reported to have a low coefficient of friction at high bearing loads and good resistance to seizing.[7]

The Reynolds Metals Co. developed a number of different types of packages which use aluminum to conserve tin and also the steel required when tin cans are used. In some of these packages, aluminum alone is used. In others, aluminum is combined with paper, wax, plastic, or fiber material to provide the kind of protection desired. Essentially the body of the can is made by winding a strip of aluminum foil into two or more layers, giving a total metal thickness sufficient for the structural requirements in the can wall.[8]

The first detinning plant ever built as a steel-company facility commenced regular operation at the Weirton Steel Co. division of the National Steel Corp. The plant was installed to conserve the company stock of tin and also to recover scrap from the tin mills which

formerly could not be used in open-hearth operations, because the coating is a contaminant. Annual capacity of the detinning plant is rated at 300,000 pounds of pig tin and 30,000 tons of bundled scrap. There is an additional recovery of tin through processing of sludge that accumulates in the plating cells of the company high-speed electrolytic lines.

Research by the Bureau of Mines on the refining of copper-tin byproduct alloy formed during operation of the United States Atomic Energy Commission Hanford plant at Richland, Wash., resulted in construction and operation of an electrolytic tin refinery by the Bureau of Mines at Albany, Oreg. A plant was designed to produce 1,000 pounds of pure tin per day at maximum capacity, and limited operations were begun on October 8, 1951.

Plant operations consisted of melting the crude alloy in a gas-fired crucible furnace and removing a high-uranium dross. The melted alloy was then cast into 300-pound anodes, which were placed in steel electrolytic cells containing an electrolyte composed of caustic soda, sulphur, and salt. Steel-cathode starting sheets were placed between the anodes to collect a pure metallic tin deposit. Periodically, the deposit was removed from the cathodes, remelted, and cast into 50-pound tin ingots.

WORLD REVIEW

INTERNATIONAL TIN STUDY GROUP

Representatives of eight major tin producing and consuming countries met in London in October 1946 and agreed that a study group should be established; in consequence, the International Tin Study Group was organized at a meeting in Brussels in April 1947. A brief report on the meetings held by the Study Group through 1951 has been published.[9] Regarding the 1951 meeting the following was given:

> The sixth meeting of the Study Group was held in Rome in September 1951. The meeting discussed the problem of international cooperation, both long term and short term. The discussion also covered prices (including the question of non-discrimination in prices), restrictions on the consumption of tin and the future functions and work of the Study Group. Mine production for 1951 was estimated at 168,000 long tons against a commercial consumption of 147,000 tons.
>
> Membership of the Study Group is confined to governments. The present membership is:
>
> Australia, Belgium, Bolivia, British Colonial and Dependent Territories, Canada, China, France, India, Indonesia, Italy, Netherlands, Thailand, United Kingdom, United States of America.
>
> The Management Committee of the Group supervises the work of the Secretariat and consists of:
>
> Belgium, Bolivia, British Colonial and Dependent Territories, France, Indonesia, United Kingdom and United States of America.

(*See* Minerals Yearbook, 1950, pages 1220 and 1221, for reports on the first five meetings.)

REVIEW BY COUNTRIES

Australia.—Production of tin in concentrates as reported totaled 1,577 long tons in 1951, a 15-percent decrease from 1950. Domestic smelter production amounted to 1,459 tons, a 28-percent decrease. The Electrochemical Metal Refining Co. Pty., Ltd., of Sydney recovered 28 tons at its detinning plant during the year. In Queensland dredging results of the largest alluvial producer in the Herberton field, Tableland Tin Dredging N. L., were disappointing.

Belgian Congo.—The year 1951 was one of great activity in the Belgian Congo, with promise of production expansion in the future. Production of tin in concentrates was 13,669 long tons compared with 13,464 (revised) in 1950. Belgian Congo, including Ruanda-Urundi, contributed 58 percent of Africa's 1951 total tin production. Tin contained in exports of concentrates totaled 9,942 long tons, of which the United States received 1,630 long tons and Belgium 8,252 long tons. Exports of metal from Belgian Congo were 2,670 long tons, of which the United States received 640 long tons and Belgium 1,962 long tons. Stocks of tin metal increased from 13 tons at the beginning of 1951 to 44 at the end. Stocks of tin in concentrates increased from 673 tons at the beginning of 1951 to 1,099 tons at the end.

An outstanding development has been the disclosure by Géomines of a huge bed of cassiterite under its Manono cassiterite opencast in Northern Katanga. The borings made have shown the existence of such huge reserves that the company stopped the boreholes after they had reached a depth of 125 metres, and had continued to show cassiterite throughout. With the tonnage already revealed, Géomines has probably the biggest tin ore reserves in the world and is assured of supplies for several decades at least. Following on these discoveries, the company decided to enlarge its capital from Fcs. B. 200,000,000 to Fcs. B. 700,000,000, so as to be enabled to work this proposition adequately. The exploitation of these deposits will be carried out in a way not to upset the tin market.[10]

Bolivia.—Bolivia exported 6 percent more tin in concentrates in 1951 than in 1950. Total tin contained in exports of concentrates in 1951 was 33,132 long tons. Nearly 51 percent was consigned to the United States and approximately 49 percent to the United Kingdom, leaving about 100 tons for delivery to Chile and Argentina. There were no great changes in the relative export shares of the several mine groups. That of Patino Mines increased from 44 percent in 1950 to 45 percent in 1951. Hochschild decreased from 23 percent in 1950 to 20 percent in 1951. Aramayo increased from 7 percent in 1950 to 8 percent in 1951. Exports of metal from the Oruro smelter were 39 tons in 1951.

The 1950 Bolivian contract with the Reconstruction Finance Corporation expired December 31, 1950, but was extended for 2 months to February 28, 1951. During the following 3 months RFC procured Bolivian ores under an interim contract which expired May 31, 1951. No tin ores were bought from Bolivian sources from that date to August 31, 1951, although negotiations were continued.

In June 1951 the RFC, in conjunction with the State Department, sent a mission to Bolivia to investigate tin-production costs and their relationship to the Bolivian economy and the world tin market. This joint mission's findings and conclusions were to be utilized in the contract negotiations with the Bolivian Government.

The RFC announced on July 24, 1951, its willingness to pay a tin price of $1.12 per pound because of higher mining costs in Bolivia.

[10] Mining Journal (London), Annual Review Edition: May 1952, p. 121.

Digitized by Google

On September 5 the Bolivian Embassy in Washington and the RFC announced that a tin contract for 30 days had been agreed upon. The price was $1.12 per pound. This price, including smelting charges, was subject to revision. On September 19 it was announced that discussions between RFC and the Bolivian Government would begin September 24. Any price established for a long-term contract was to be retroactive to June 1, 1951, in regard to all tin delivered to the RFC under this new contract. Negotiations for a long-term contract with the Bolivian producers were held intermittently and their conversations with RFC officials entered a period of recess on October 11. At the end of the year a long-term contract was still to be negotiated.

Receipts of Bolivian ore at the Texas City smelter during the calendar year 1951 were:

	Ore		Tin	
	Long tons	Percent tin	Long tons	Percent total tin content
High-Grade	8,658	59.27	5,132	39.49
Medium-Grade	8,141	46.71	3,803	29.27
Low-Grade	19,435	20.89	4,060	31.24
Total	36,234	35.86	12,995	100.00

Brazil.—The Brazilian Department of Mineral Production (DNPM) has intensified investigation of the cassiterite deposits in the Rio das Mortes Basin, Minas Gerais. Local mining companies have operated, and new refining processes have been introduced by the Empresa Mineira de Estano, the largest producer. The Sao Joao del Rei deposits, discovered in 1942, contain cassiterite with a tin content of 66 to 73.2 percent. The two principal mines (Paiol and Rio Abaixo) have reserves of about 9,000 tons.

Burma.—Production of tin in concentrate was estimated at 1,624 long tons in 1951, a 7-percent decrease from 1950. Exports of tin in concentrate were about 1,477 long tons, of which 1,335 was shipped to Malaya for smelting. The Burmese political situation has been so disturbed since World War II that the 1951 tin output was only about one-fifth of the prewar level of 5,000 tons per year. To cite a typical example—the Tenasserim Peninsula coast area was formerly exploited for tin and tungsten ores by 8 or 10 small companies and numerous independent operators. These activities were suspended because of the continued unstable conditions. M. S. Han & Co. is mining tin and tungsten ores from its properties near the rail line just north of Thaton, about 35 miles north of Moulmein.

Conditions in the tin-mining district of lower Burma brought mining to a standstill. European staffs were, by Government order, confined to Tavoy town and not allowed to proceed to the mines for security reasons.

Indonesia.—In 1951, Indonesia was the third largest tin producer in the world. Production of tin in concentrates totaled 30,986 long tons, a 3-percent decrease from 1950. The Indonesian output of tin represented 18 percent of the world total. Tin production in Indonesia is confined to the islands of Banka, Billiton, and Singkep, which in 1951 supplied 63, 28, and 9 percent of the total, respectively.

Digitized by Google

Exports of tin in concentrates were 30,750 long tons, of which 21,110 was shipped to the Netherlands, 9,439 tons to the United States, and 201 tons to Malaya. The principal methods of mining alluvial tin deposits in Indonesia are dredging, gravel pumping, and hydraulicking. Over two-thirds of the production now comes from dredges and under one-third from gravel pumps and hydraulicking. The Chinese tributers treat on lease poorer or previously worked grounds unsuitable for larger scale European methods. In 1951, the tributers produced about 3 percent of the total production. Data on the number of producers, as of December 30, 1951, is set forth as follows:

Number of dredges operating	29
Gravel pumping and hydraulicking (number of mines operating)	65
Labor employed	22,526
Staff employed	1,090

Malaya.—During 1951 Malaya earned about 500 million United States dollars, of which rubber and tin accounted for about 90 percent.[11] Tin reached the all-time record of $783 (Malayan dollars) a picul (133⅓ pounds). The average for the year was $537—an increase of 44 percent over the 1950 average. The Commonwealth's greatest dollar earner was subjected throughout the year to terrorist activities on a widespread scale. By the end of 1951 an overall improvement in the general emergency could be discerned, and there were grounds for believing that this improvement was likely to be maintained.[12]

Mine production of tin in concentrate was 57,167 long tons in 1951 compared with 57,537 in 1950, 84,082 in the peak year 1940, and an annual average of 55,309 per year during the prewar period 1935–39.

Economically, one of the most serious aspects of the emergency is the interference with railway traffic which resulted from unstable political conditions. As a result of this situation, exploration has been almost completely arrested.

The number of dredges operating has increased steadily since 1947, although the average annual output per dredge has not recovered to the prewar level.

	1929	1933	1940	1948	1951
Number of dredges operating	105	23	104	63	83
Average annual output per dredge (tons of fine tin)	259	468	406	348	372

About 87 percent of the total Malayan production of tin in 1951 was obtained by dredging (52.6 percent) and gravel pumping (34.3 percent). The percentages from other methods of mining were hydraulicking, 3 percent, opencast mining 4 percent, underground mining 5 percent, dulang washing 1 percent.

In 1951 an analysis of dredge data shows that 67 dredges, for which both yardage and concentrate production are given, recovered 30,938.71 tons of concentrates (75 percent tin-content basis) from the washings of 143,305,351 cubic yards of gravel, or 0.36 pound of tin metal in concentrates per yard washed. The dredges for which yardage data were unavailable recovered 4,999.2 tons of concentrate.

[11] Mining Journal (London), Annual Review Edition: May 1952, p. 143.

Thus, the average content figure is based on 86.1 percent of the concentrate recovered by dredging.

The smelting of tin ores in Malaya is carried on by two large companies—the Eastern Smelting Co., Ltd., with a smelter in Penang, and the Straits Trading Co., Ltd., with a smelter in Singapore. A negligible quantity of concentrates is smelted by a Chinese smelter for local consumption.

These plants decreased their output 4 percent and supplied 39 percent of the world smelter production in 1951. Concentrates treated were derived mostly from Malaya, with smaller tonnages from Thailand, Burma, Indonesia, and French Indochina. The tin content of concentrates available from Malaya was 57,167 long tons compared with 57,537 in 1950. Imports originating elsewhere contained 7,731 tons of tin against 9,912 in 1950. The plants shipped 64,956 tons of metal (about 56 percent from Penang and 44 percent from Singapore). Only 4 percent went to the United States in 1951. Stocks of tin metal increased from 1,991 at the beginning of 1951 to 2,852 at the end, while stocks of tin in concentrates decreased from 4,521 at the beginning to 4,488 at the end.

A United States mission for the study of problems in tin visited Malaya and Singapore on the invitation of the Government of Malaya, transmitted through and endorsed by the British Government.

The mission arrived at Singapore on November 6, 1951, and completed its study November 17. During that time it examined tin mines, smelters, and tin marketing in Malaya and in Singapore. The conclusions of the report are quoted as follows:

1. The emergency, as the guerrilla activities in Malaya are termed, was found to pervade every phase of Malayan life. Exploration for tin deposits and production expansion have been arrested. The casualty lists for Government forces and civilians, as well as for guerrillas, have reached into the thousands; the recorded dead exceeded five thousand before the end of September 1951.

In all considerations of future tin supply it must be recognized that Malaya, the world's largest producer, is a focal point in Communist aggression. Substantial success by these elements in Malaya could very easily engulf the country's tin producing neighbors with the result that well over one-half of the world's production might, in a surprisingly short time, become unavailable, except on Communist terms.

2. The Mission did not discover any evidence of curtailment of tin output by the mining or smelting industries. However, the emergency has arrested output expansion and interferes with efficient production. Until the emergency is brought under control, no substantial production expansion for tin can be expected.

3. Exploration has been almost completely arrested. The tin mining industry is rapidly depleting its reserves available under present technology and price levels. Perhaps most depressing of all aspects of the Malayan tin situation is the certainty of a declining output in the fairly near future, unless the problem of developing reserves to replace current depletion can be solved.

4. Proposals by the Mission as a group and as individuals that alternate methods of tin procurement be developed were countered by mining, smelter and Government representatives that the Singapore market be given a fair trial as an exclusive medium for procurement from Malaya before alternatives be discussed. Although the Mission pressed the point that the Singapore market might be unacceptable in Washington, the Malayan representatives maintained their position.

In the Mission's explorations of alternatives the following principles were put forward: That a term contract for a substantial quantity at a fixed price subject only to price index escalation be basic; that tin be delivered either as metal through a toll agreement with Malayan smelters or as concentrates; that any master contracts with large mine producers be available to any other producers no matter how small who might choose to subscribe; and concurrence of Governments involved would be acceptable if necessary.

Digitized by Google

Although the Malayan representatives admitted the feasibility of Mission suggestions, no willingness to permit the proposals to be conclusive developed.

5. The population of Malaya is approximately one-half native Malay, two-fifths Chinese and one-tenth Indian. This composition complicates political development * * *.

The present form of government in Malaya, the second to be established in the post-war period, is only three years old and apparently is still in a state of evolution. Tin output could be affected substantially by governmental change.

6. The development of the Federation of Malaya toward self-government has proceeded to such a degree that the wishes of local representation on the Council must be given serious consideration. Although the United Kingdom Government retains the authority to intervene in economic affairs, in practice any governmental arrangements involving tin probably would require the acquiescence of the Legislative Council of the Federation.

7. The steady post-war uptrend of the average wage scale indicates the gradual elimination of cheap common labor in the mining industry. It portends for the future an acceleration of mechanization with the resultant increase in capital investment and an increase in the proportion of skilled to unskilled labor at mines and smelters.

8. The mining technology appears to be thoroughly modern varying from United States placer practice only in response to difference in product, difference in nature of deposits, availability of very cheap labor, high power costs, availability of local materials and other such factors. The only technical possibility for substantially increased output seems to lie in the devising of a method for recovering very fine tin now being discharged in the slime tailings.[13]

Nigeria.—Production of tin in concentrate in Nigeria totaled 8,555 long tons in 1951, a 4-percent increase from 1950. In 1951 tin production was in the hands of 39 companies (mainly registered in the United Kingdom) and 76 individual owners (mainly Europeans in Nigeria). Only 6 of the companies had an output of over 300 tons; about 45 percent of the total output came from the Amalgamated Tin Mines of Nigeria, Ltd. The Nigerian industry is not highly mechanized (there is only one dredge in the territory), and about half its output still comes from small mines worked by tributers. The whole of the production is exported as concentrate to smelters in the United Kingdom. The grade in 1939 was 2.26 pounds of cassiterite per cubic yard, in 1948 only 1.01 pounds, and in 1950–51, 0.76 pound. It is hoped that additional reserves of good-grade tin lie in the deep deposits under the basalt layers on the Nigerian Plateau, and some companies have undertaken proof drillings and constructed prospect adits on these hard layers to reach the deposits at depths varying from 70 to 150 feet.

Reserves of cassiterite amounted to approximately 100,000 tons of proved and 33,000 tons of indicated mineral. Assuming a recovery of 70 percent metal after smelting, this would represent about 93,000 tons of tin. On the basis of the present annual output, say 10,000 tons, this would give a life of 9 years for the known Nigerian deposits (assuming no additional reserves were developed).[14]

Thailand.—Production of tin in concentrates in 1951 totaled 9,502 long tons, an 8-percent decrease compared with 1950. The number of dredges operated decreased from 31 in January to 28 in December. In 1951 production of tin in concentrate from dredges amounted to 5,525 long tons or 58 percent of total output; production from gravel pumps and hydraulicking amounted to 2,252 tons or 24 percent of total output. Production from other means and from dulang washing accounted for 899 tons or 9 percent, and 827 tons or 9 percent,

[13] Bureau of Mines Mineral Trade Notes, United States Tin Mission Report; Malay, 1951: Spec. Suppl. 39 (to vol. 35, No. 3), September 1952, pp. 1–3.

Digitized by Google

respectively, of total output. European mines accounted for 60 percent, Thailand mines for 38 percent, and Chinese mines for 2 percent of total production in 1951. Exports (reported as imports by receiving countries stated) of tin in concentrates were 8,809 long tons, of which 2,727 was shipped to the United States, 6,003 to Malaya, and 79 tons to the Netherlands.

An excellent description of the tin deposits and tin industry of Thailand was published in 1951, as a result of a joint investigation by the Royal Thai Department of Mines and the United States Geological Survey.[15]

United Kingdom.—Mine production totaled about 1,210 tons in 1951 compared with 1,230 tons in 1950. United Kingdom smelter production of tin was the third largest in the world in 1951. Output declined 3 percent compared with 1950. Year-end stocks of tin in concentrate were 1,923 tons (2,250 at beginning of year) and of metal 8,004 tons (11,504 at the beginning). Total stocks including tin metal and concentrates afloat and visible consumers' stocks were reported to be 13,300 tons at the end of 1951—a 15-percent decrease from 15,600 tons at the beginning of the year. Total virgin tin consumed was 23,892 tons, 3 percent above 1950. The following table provides data on the consumption of virgin tin in 1950 and 1951 by principal trades.[16]

	1950	*1951*
Tin plate	9,821	9,417
Tinning	1,373	1,475
Solder	2,798	3,277
Alloys:		
White metal	4,017	4,372
Bronze and gunmetal	2,504	2,825
Other	433	442
Wrought tin	1,260	948
Chemicals	908	971
Other uses	140	165
Total, all trades	23,254	23,892

Titanium

By Frank J. Cservenyak and Alfred Tumin

GENERAL SUMMARY

DOMESTIC production of titanium dioxide pigments, ilmenite, and titanium metal established new peak records in 1951. The production of titanium dioxide pigments continued to be the basis of the titanium industry; however, considerable progress was made in production of titanium metal. Consumption of rutile, mainly in welding-rod coatings and alloys, almost equaled the record established in 1943.

Considerable research was conducted by industry and the Government on production and utilization of titanium metal and its alloys. Although the production increased from about 75 short tons in 1950 to 495 tons in 1951, the price of titanium sponge remained unchanged at $5 per pound, and most of the production went into research and development of military items. This price necessarily limited widespread civilian use of titanium. Continued expansion of titanium metal production for civilian as well as military uses was expected if substantial reductions could be made in production and fabricating costs. Development of high-temperature titanium alloys and information on properties and uses of the metal and its alloys was also necessary for realization of the numerous potential applications.

Increased domestic production of ilmenite, supplemented by titanium slag imports from Canada, increased the United States readily available supply of materials for production of titanium dioxide pigments and future source materials for the production of titanium metal.

The supply of rutile was reported to be limited at the end of 1951. The increased demand for rutile was met in part by increased imports from Australia and significant reductions in producers' and consumers' stocks.

RESERVES

A preliminary unpublished report was prepared in 1951 on the titaniferous iron deposits of the Laramie Range, Wyo. Titaniferous iron deposits located 15 miles northeast of Laramie, Wyo., to a few miles beyond North Sybille Creek, Wyo., contain magnetite-ilmenite bodies and were reported to be large enough to be of commercial interest. Although deposits are known to occur at more than 30 places in this area, most of the exposures are small. These deposits have been divided into the following three grades: Grade 1, consisting of massive ilmenite with 0 to 35 percent by volume of silicates, mostly olivine and some spinel, containing 16 to 23 percent TiO_2; Grade 2,

Digitized by Google

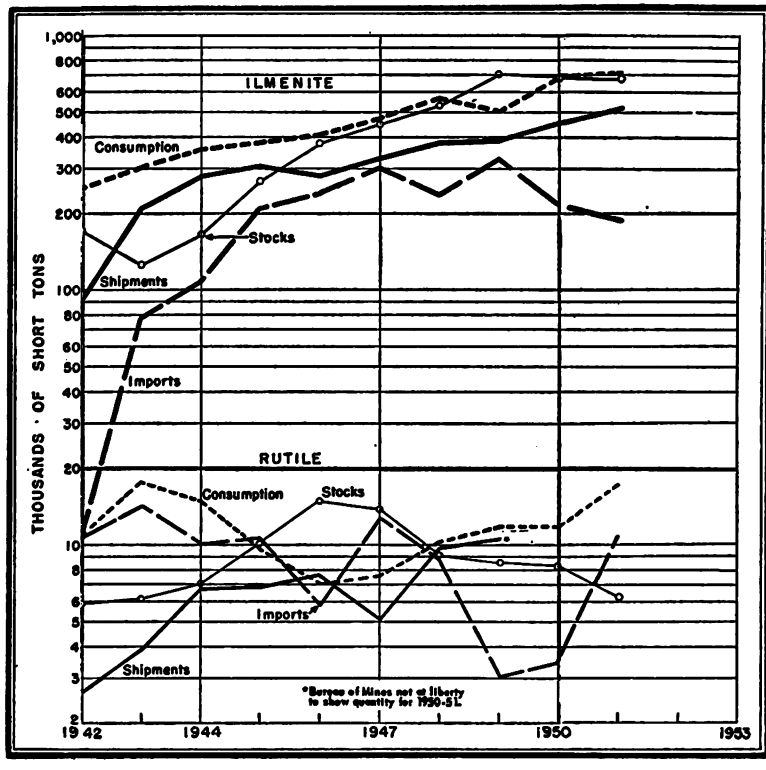

FIGURE 1.—Domestic shipments, imports, consumption, and stocks of ilmenite and rutile, 1942–51.

consisting of magnetite-ilmenite with 35 to 65 percent by volume of silicates, chiefly olivine and some spinel, plagioclase, and hypersthene, containing 10 to 16 percent TiO_2; Grade 3, consisting of magnetite-ilmenite with 65 to 85 percent by volume of silicates, largely plagioclase with olivine and hypersthene, containing 5 to 10 percent TiO_2. The principal tonnage is found in two blocks designated as the northern and southern areas. All of the ore estimated in the northern area occurs at an elevation of more than 6,900 feet and in the southern area at an elevation of more than 6,600 feet. There are approximately 9,150,000 short tons of indicated and inferred titaniferous magnetite ore in the main ore zone. Of this total, 8,650,000 tons is in the northern and southern blocks; the remaining 500,000 tons is in small lenses and masses. Deeper ore may be present in the structure occupied by the northern and southern ore bodies of Iron Mountain.[1]

Ilmenite was produced in 1951 as a byproduct from operations at Cascade, Idaho, concerned primarily with production of monazite and other materials. It was estimated that 3 deposits in the Long Valley area of Valley County, Idaho, total 150 to 200 million cubic yards of gravel containing 8 to 10 pounds of ilmenite per cubic yard.

[1] Newhouse, W. H., and Hagner, A. F., Preliminary Report on the Titaniferous Iron Deposit of the Laramie Range: U. S. Geol. Survey open file rept., 1951 (unpublished).

Digitized by Google

Reserves in Central Valley County deposits were estimated at 400 million cubic yards containing 15 to 30 pounds of ilmenite per cubic yard.

DOMESTIC PRODUCTION

CONCENTRATES

Production and shipments of ilmenite in 1951 were 535,835 and 510,840 short tons, respectively, an increase of 14 percent in production and 13 percent in shipments; both established new records for the fifth successive year. In the record-breaking years since 1947, ilmenite production increased 59 percent, while shipments increased 52 percent. Of the total ilmenite production New York continued to supply more than one-half, Florida about one-third, and North Carolina, Virginia, and Idaho the remainder.

Ilmenite in 1951 included a small quantity of mixed product containing altered ilmenite, leucoxene, and rutile. The mixed product was used in the manufacture of both titanium pigments and metal. Shipments of ilmenite ranged from 43 to 66 percent TiO_2 and rutile from 93 to 97 percent TiO_2.

TABLE 1.—Production and mine shipments of titanium concentrates from domestic ores in the United States, 1946–51, in short tons

Year	Ilmenite				Rutile			
	Production (gross weight)	Shipments			Production (gross weight)	Shipments		
		Gross weight	TiO_2 content	Value		Gross weight	TiO_2 content	Value
1946	282,447	282,708	130,624	$4,878,917	7,453	7,514	7,046	$996,989
1947	336,533	336,061	157,328	5,029,490	8,562	5,175	4,813	533,548
1948	383,745	381,508	177,447	5,793,973	7,380	9,907	9,226	647,334
1949	402,334	389,234	186,535	6,212,348	[1] 11,988	[1] 10,559	[1] 9,414	[1] 489,798
1950	[1] 468,320	[1] 452,370	[1] 230,826	[1] 5,606,584	(2)	(2)	(2)	(2)
1951	[1] 535,835	[1] 510,840	[1] 261,982	[1] 7,689,272	(2)	(2)	(2)	(2)

[1] Includes a mixed product containing altered ilmenite, leucoxene, and rutile.
[2] Figures withheld to avoid disclosure of individual company operations.

Florida.—The E. I. du Pont de Nemours & Co. property at Starke, Fla., produced ilmenite and a mixed product containing altered ilmenite, leucoxene, and rutile. Production at this property in 1951 increased about one-fourth over that in 1950.

The Rutile Mining Co. of Florida near Jacksonville and the Florida Ore Processing Co., near Melbourne, continued to produce rutile and ilmenite in 1951.

Idaho.—Ilmenite was produced by Baumhoff-Marshall, Inc., at Cascade, Idaho. Shipments in 1951 from this property were consumed for purposes that did not require a titanium content. The Idaho-Canadian Dredging Co. at Cascade, Idaho, began ilmenite operations at the end of 1951.

New York.—Production of ilmenite at Tahawus, Essex County, N. Y., by the National Lead Co. in 1951 exceeded the peak established in 1949.

Digitized by Google

North Carolina.—The Yadkin Mica & Ilmenite Co., subsidiary of the Glidden Co., produced ilmenite at Finley, Caldwell County, N. C. Production from this property in 1951 established a new record, slightly exceeding the previous peak in 1949.

Virginia.—Ilmenite was produced in 1951 at Piney River, Nelson County, Va., by the Calco Chemical Division of the American Cyanamid Co. Production at this property in 1951 was slightly higher than that in 1950.

METAL

Production of titanium sponge in 1951 was 495 short tons coming from plants operated by E. I. du Pont de Nemours at Newport, Del.; Titanium Metals Corp. of America at Sayreville, N. J., Niagara Falls, N. Y., and Henderson, Nev.; and leased facilities at the Bureau of Mines pilot plant, Boulder City, Nev.; and the Crane Co. at Chicago, Ill.

Du Pont began operating a commercial plant in May with a nominal capacity of 2 short tons of titanium sponge per day. The production rate originally estimated was reached in the latter part of 1951. Du Pont planned to reach an expected capacity of 2½ tons per day at this plant in 1952. At the request of the Government the General Services Administration was negotiating with du Pont for additional expansion in 1952.

Metal Hydrides, Inc., Beverly, Mass., produced 144,271 pounds of titanium powder in 1951 by reduction of titanium oxide with calcium hydride. This company supplied titanium as powder, titanium hydride, and titanium master alloys. The titanium powder is reported to be easily compressed into suitable forms and sintered either in vacuum or in a nonoxidizing atmosphere into solid blocks or finished products at as low as 900° to 1,000° C.

The Foote Mineral Co., Philadelphia, Pa., installed capacity for the production of extremely pure titanium by thermal decomposition of volatile titanium iodides. It offered, for research purposes, titanium crystal bar containing 99.9 percent Ti, approximately ½ inch in diameter by 19 inches in length (maximum).

New titanium organizations were formed in 1951. The National Research Corp., of Cambridge, Mass., and Monsanto Chemical Co. joined forces to develop an improved process for the production of titanium. Work already in process by National Research was expanded, and additional work was initiated by Monsanto's research department at Dayton, Ohio. P. R. Mallory & Co. and the Sharon Steel Corp. formed the Mallory-Sharon Titanium Corp. for the development, production, and marketing of titanium and titanium alloys. A new process for producing titanium metal was being investigated by Horizons Titanium Corp., a new firm formed by Horizons, Inc., of Princeton, N. J. backed by Ferro, Inc., of Cleveland, Ohio, and others. The process developed by Horizons, Inc., under the sponsorship of the Office of Naval Research, had advanced to the pilot-plant stage at the end of the year. The Kennecott Copper Corp., after having investigated several processes during the past several years, developed a process on a laboratory scale, which showed possibilities of yielding superior-quality metal, with certain production advantages over the present process. A pilot plant to evaluate the process on a scale of about 200

Digitized by Google

pounds per day was under construction at Battelle Memorial Institute in 1951 and was expected to begin operations around the middle of 1952.

The Titanium Metals Corp. of America, jointly owned by National Lead Co. and Allegheny Ludlum Steel Corp., signed a letter of intent in August 1951 for construction and operation of a plant to produce 3,600 tons of titanium per year for 5 years. An advance of $15 million was made to the Titanium Metals Corp. by the Government. This advance, plus interest at 4 percent per annum on the unpaid balance, was repayable either in dollars or in titanium metal. Titanium sponge acceptable to the Government was to have the following specifications: Titanium content, 99.3 percent minimum; total maximum impurities, 0.7 percent; iron, 0.25 percent maximum; nitrogen, 0.03 percent maximum; chlorides, to be established from operating and storage experience; and hardness after arc melting in an inert atmosphere, less than 250 Vickers or 61 Rockwell A. The site of the new operation is the former Basic Magnesium, Inc., plant at Henderson, Nev., built by the Government during World War II. Major components of this plant were leased from the State of Nevada. Power is to be allocated from Hoover and Davis Dams, up to a maximum of 151 million kw.-hr., by the Colorado River Commission from the quota allotted to the State of Nevada. The Henderson plant is the first fully integrated titanium plant with facilities for chloridation of titanium ore and recovery of magnesium and chlorine by electrolysis of magnesium chloride. The Henderson plant began initial operations in September 1951 and routine production in October.

The chief producers and suppliers of commercial grades of titanium-base alloys in various forms in 1951 were Rem-Cru Titanium Inc., Midland, Pa.; Titanium Metals Corp. of America, New York, N. Y.; and Mallory-Sharon Titanium Corp., Niles, Ohio.

CONSUMPTION AND USES

Consumption of ilmenite increased 5 percent in 1951, establishing a new record of 713,363 tons. Except in 1949, ilmenite consumption has increased steadily each year since 1942, when it was 257,535 tons. The manufacture of pigments, following the pattern of previous years, accounted for 99 percent of all ilmenite consumption. Ilmenite consumption in 1951, as in 1950, included a mixed product containing altered ilmenite, leucoxene, and rutile. The consumption of rutile in 1951 increased 47 percent over 1950 and almost equaled the record established in 1943. Increases were noted in new uses of rutile for titanium metal and fiber glass, which are reported under miscellaneous uses.

Titanium Pigments.—Production and shipments of titanium pigments in 1951 were 5 and 2 percent, respectively, above 1950 and established another new peak. Figures in this industry are supplied in confidence and consequently are not given here. However, the percentage distribution of titanium pigment shipments, by consuming industries, is shown in table 3.

Welding-Rod Coatings.—Production of titanium-coated welding rods was 287,065 short tons in 1951, an increase of 53 percent over the 188,000 tons in 1950; 154,000 tons was coated in 1949, 188,000 tons in 1948 and 481,000 tons in the record year 1943. Of the 1951 tonnage, 61 percent was coated with natural rutile, 15 percent with manufac-

Digitized by Google

tured titanium dioxide, 18 percent with both varieties, and 6 percent with ilmenite.

The General Electric Co. developed a process whereby titanium hydride is used to solder glass to metal and metal to ceramics and carbon, forming a strong bond. The areas soldered were painted with a thin layer of titanium hydride, and solder was placed upon both painted areas. The parts were placed together and heated to 900° F., under vacuum, to decompose the titanium hydride and cause the molten solder to adhere to both surfaces. The new technique was reported in use in aircraft ignition systems, and laboratory investigations suggested possible applications in the manufacture of transformers, capacitors, and electric motors.[2]

TABLE 2.—Consumption of ilmenite and rutile in the United States, 1942–48, total, and 1949–51, by products, in short tons

Product	Ilmenite		Rutile	
	Gross weight	Estimated TiO_2 content	Gross weight	Estimated TiO_2 content
1942	257,535	141,412	10,616	9,952

Titanium and its alloys offer special advantages for civilian use and military equipment because of their unusual combination of properties—lightness, strength, and resistance to corrosion. Tests were actively under way in 1951 on the use of titanium in civilian and military equipment.[3]

Reports and studies indicated that titanium metal would find use in the following fields:

1. Aircraft power plants: Its light weight and strength are needed here. Also, titanium can withstand the increasingly higher operating temperatures better than aluminum alloys.
2. Aircraft frames: As speeds increase, aircraft frames must be stronger and withstand higher temperatures. Titanium fits these requirements.
3. Pyrotechnics: Titanium powder burns in air with intense heat. This probably will be a small market.
4. Low-titanium alloys: A number of iron and nonferrous alloys include 0.1 to 3.5 percent titanium. The use of higher purity metal in these alloys enables producers to obtain cleaner and stronger alloys with greater regularity.
5. Marine equipment: Titanium is highly resistant to sea-water corrosion.
6. Chemical equipment: Titanium is generally resistant to corrosion, particularly by oxidizing, chlorine, and chloride reagents.
7. Ordnance: Unalloyed titanium is reported to be more resistant to projectiles than any armorplate now in existence.

STOCKS

Inventories of ilmenite decreased slightly in 1951 and at the end of the year were equivalent (TiO_2 content basis) to about 11 months' requirements at the record rate of consumption in 1951. Rutile stocks dropped 24 percent in 1951 and at the end of 1951 were sufficient to sustain industry at the 1951 rate of use (TiO_2 content basis) for 4 months. Significant decreases in year-end stocks of rutile were reported by some welding-rod coatings, alloys, and carbide producers.

TABLE 4.—Stocks of titanium concentrates in the United States at end of year, 1950–51, in short tons

Stocks	1950[1]				1951			
	Ilmenite		Rutile		Ilmenite		Rutile

PRICES

Ore.—Quotations, in E&MJ Metal and Mineral Markets for 1951, per long ton for ilmenite containing 56 to 59 percent TiO_2, f. o. b. Atlantic seaboard, according to grade and impurities, were $14–$16 at the beginning of 1951, $15–$17 in January, and $16–$18 in February, at which level they remained for the rest of 1951. Quotations were nominal. For rutile concentrates, guaranteed minimum 94 percent TiO_2 content, they were 3½–4½ cents per pound until November 29, 1951, when they increased to 5¼–6¼ cents per pound. Rutile was covered by General Ceiling Price Regulation, which established ceiling prices upon the basis of prices in effect during the base period December 19, 1950, to January 25, 1951. The year closed with a ceiling price for rutile concentrate averaging about 5 cents per pound, east coast ports.

Ferrotitanium.—Prices quoted in the magazine Steel at the beginning of 1951 were in effect until January 22, 1951, when all ferrotitanium prices increased. The increased quotations continued for the remainder of 1951. Ferrotitanium price quotations at the beginning of the year and on January 22, 1951, are shown in the following tabulation:

Digitized by Google

	Jan. 1, 1951	Jan. 22, 1951
Ferrotitanium, Low-Carbon, f. o. b. Niagara Falls, N. Y., freight allowed to St. Louis, spot add 5¢:		
(Ti, 20–25 percent; Al, 3.5 maximum; Si, 4 percent maximum; C, 0.10 percent maximum). Contract, 2″ x D, per pound of contained Ti:		
Ton lots	$1.40	$1.50
Less-than-ton lots	1.45	1.55
(Ti, 38–43 percent; Al, 8 percent maximum; Si, 4 percent maximum; C, 0.10 percent maximum). Contract, per pound:

Less-than-ton lots	1.35	1.37
Ferrotitanium, High-Carbon: (Ti, 15–18 percent; C, 6–8 percent). Contract per net ton, f. o. b. Niagara Falls, N. Y., freight allowed to destination east of Mississippi River and north of Baltimore and St. Louis	167.00	177.00
Ferrotitanium, Medium-Carbon: (Ti, 17–21 percent; C, 3–4.5 percent). Contract per ton, f. o. b. Niagara Falls, N. Y., freight not exceeding St. Louis rate allowed	183.00	195.00

Metal.—Titanium powder, 96, 97, and 98.5 percent Ti, was quoted in the American Metal Market during 1951 at $5, $6, and $7 a pound, respectively, f. o. b. Beverly, Mass. Titanium sponge metal prices, as quoted by E. I. du Pont de Nemours & Co., Pigments Department, Wilmington, Del., remained the same as in 1950—$7.50 per pound in quantities of less than 100 pounds and $5 per pound in quantities of 100 pounds or more, all prices f. o. b. shipping point. Titanium metal prices for commercially pure and alloy grades, as quoted in Steel magazine and by the Titanium Metals Corp. of America, New York, N. Y., also remained the same during 1951: Base prices per pound in lots of 10,000 pounds and over in commercially pure and alloy grades f. o. b. mill: Hot and cold-rolled sheets, $15, Brackenridge, Pa.; hot-rolled sheared mill plate, $12, Brackenridge; cold-rolled strip, $15, West Leechburg, Pa.; rolled or cold-drawn round bar in small diameters and round wire, $10, Dunkirk, N. Y; forgings (rounds, disks, and round-cornered squares and rectangles), $6, Watervliet, N. Y.; hot-rolled bars (rounds, flats, and squares), $6, Watervliet. Extremely pure titanium produced by the iodide process was quoted by the Foote Mineral Co., Philadelphia, Pa., at $95 per pound in lots of 100 pounds and up and $125 per pound in lots of less than 100 pounds, f. o. b. Exton, Pa., with a minimum order of $10. This metal was available in crystalline bars approximately ½ inch in diameter by 19 inches in length (maximum).

Manufactured Titanium Dioxide.—Manufactured titanium dioxide (anatase), ceramic, chalk-resistant, and regular grade in bags, carlots, and delivered, were quoted by Oil, Paint and Drug Reporter throughout 1951 at 21–21½ cents per pound. Rutile, nonchalking, was quoted at 23–23½ cents during 1951.

FOREIGN TRADE [4]

Imports.—Receipts of ilmenite in 1951 were 189,078 short tons, 13 percent less than the 1950 total of 216,459 tons, 42 percent less than the record of 324,157 tons established in 1949, and the lowest since the 1944 total of 104,884 tons. Imports from India, the dominant source, dropped slightly. Canadian imports, consisting mostly of titanium slag, almost tripled in quantity. Norway, the second major source of ilmenite in 1950, did not supply any ilmenite to the United States in 1951. Rutile imports for 1951 were 11,023 short tons, over 3 times the 1950 total of 3,427 tons. The 1951 total was the largest since 1947, when 12,637 tons was imported. All imports of rutile were from Australia for the fourth successive year. Ilmenite and rutile remained free of tariff duties in 1951.

TABLE 5.—Titanium concentrates [1] imported for consumption in the United States, 1942–46 (average) and 1947–51, by countries, in short tons

[1] Classified as "ore" by the U. S. Department of Commerce.
[2] Most of the imports of titanium from Australia in 1940–47 were in mixed zircon-rutile-ilmenite concentrates, which were included as ilmenite, rutile, and zirconium ore in U. S. Department of Commerce figures. The quantities reported by the U. S. Department of Commerce have been adjusted to reflect percentage content of each item based on reports to the Bureau of Mines from importers.
[3] Less than 0.5 ton.
[4] Includes titanium slag containing approximately 70 percent TiO_2.

[4] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Exports.—Exports of titanium dioxide and pigments in 1951 established a new record of 39,242 short tons, an increase of 20 percent over the previous peak in 1950. Canada was the major recipient of titanium pigments from the United States in 1951, receiving 25,983 short tons. Other countries that received 1,000 short tons or more were as follows: Brazil, 1,724; Mexico, 1,576; Argentina, 1,223; Netherlands, 1,178; Cuba, 1,102 and France, 1,003. The remainder was distributed among 41 other countries. Exports of titanium concentrates increased from 600 tons in 1950 to 646 short tons in 1951. Canada received 592 tons of concentrates, and 4 other countries received small amounts. Exports of titanium ferroalloys in 1951 were 175 short tons, a slight increase over 1950. Canada received 164 short tons and 7 countries the remaining 11 tons. This increase in exports of ferroalloys was the first since 1944. Total titanium products exported in 1951 were valued at $13,444,911; tetrachloride and other compounds are no longer classified separately and are not included in this total.

TABLE 6.—Exports of titanium products from the United States, 1946–51, by classes

[U. S. Department of Commerce]

Year	Concentrates		Ferroalloys		Dioxide and pigments	
	Short tons	Value	Short tons	Value	Short tons	Value
1946	1,385	$200,866	550	$63,723	16,314	$3,092,607
1947	1,266	192,703	509	80,590	21,171	5,183,936

TECHNOLOGY

Smelting tests to remove iron from titaniferous iron ores by electric smelting, on a pilot plant scale, were carried out successfully by the Bureau of Mines laboratory at Boulder City, Nev. Approximately 15 tons of titanium slag running 65 to 70 percent TiO_2 was produced from titaniferous ores containing 30 to 45 percent TiO_2. The solubility of titanium slag in sulfuric acid indicated that it would be acceptable as a raw material for the production of titanium pigment. The iron content of the ore, which by chemical treatment would be converted to cheap ferrous sulfate, was obtained as a pig iron of better potential market and strategic value.[5]

The zirconium-titanium system was investigated by the Bureau of Mines laboratory at Albany, Oreg., over the entire range of compositions from 100 percent zirconium to 100 percent titanium, using both graphite-melted and arc-melted alloys. Maximum strengths were developed in 50-percent atomic composition in the hot-rolled, quenched, and annealed condition. Tensile strengths of the graphite-

Digitized by Google

melted alloys were 158,000 pounds per square inch. The resistance of these alloys to high temperatures was extremely poor.[6]

Experimental studies were conducted by the Bureau of Mines laboratory at Pittsburgh, Pa., to determine the explosive properties of titanium, zirconium, thorium, uranium, and their hydrides. Results of these tests disclosed that dust clouds of the powders in air constituted severe potential explosion hazards and indicated the advisability of processing and handling several of these powders in the dry state under helium or argon gas.[7]

As in 1950, commercial production of titanium metal in 1951 was based on modifications of the Kroll process, developed by the Bureau of Mines, involving reduction of titanium tetrachloride with magnesium. Considerable research and development work on titanium was carried out in 1951 under Government sponsorship or by private interests. A list of projects included under this research was drawn up by the Metallurgical Advisory Committee on Titanium.[8]

An article in Chemical Engineering reviewed titanium metal developments in 1951.[9] Considerable attention was given to the consolidation of sponge titanium to ingot, a problem involving the high melting point of titanium and the necessity of avoiding oxygen and other contaminants such as nitrogen, carbon, or iron. Several articles reported progress in melting titanium. An automatic continuous-casting arc furnace employing a nonconsumable electrode and a d. c. arc was operated successfully to melt commercially pure titanium sponge at a rate of 0.6 to 1.0 pound per minute with a power input of 64 to 100 kw.[10] Development of a tilting-type furnace using a graphite crucible, under vacuum or inert atmosphere, with high-frequency induction heating for melting titanium was reported.[11]

As titanium will be utilized mainly in the form of titanium base alloys, investigations were conducted in 1951 on alloying titanium metal with other metals.[12]

The fabrication of titanium requires different techniques than for other comparable hard metals. Considerable progress was reported during the year on machining and forming titanium and its alloys.[13]

A report at the end of the year described the use of spiral concentrators and electrostatic-magnetic separators at the Trail Ridge, Fla., titanium mineral concentrating plant to recover ilmenite, leucoxene, and zircon from beach sands near Starke, Fla. The Trail Ridge mine and plant are owned by E. I. du Pont de Nemours & Co. The plant was built by Humphreys Gold Corp. and was operated by that company for du Pont.[14]

A new series of titanium-base carbides containing nickel or cobalt auxiliary metal with small amounts of columbium and tantalum carbide was developed by Kennametal, Inc., Latrobe, Pa. The carbides known as Kentanium were developed for use in applications requiring strength and shock resistance under high-temperature operating conditions. Test information on Kentanium and on work done at Ohio State University on cermets of the same category was reported.[15]

WORLD REVIEW

World production of ilmenite and rutile in 1951 was estimated at 800,000 and 42,000 metric tons, respectively, and established new records. Ilmenite production increased slightly, while rutile production was about two-thirds above the 1950 output.

The United States continued to be the world's largest producer of ilmenite, accounting for nearly two-thirds of ilmenite produced in 1951. Australia continued to lead in the production of rutile.

Available data on world production of ilmenite and rutile in recent years, with revised figures, are shown in table 7.

TABLE 7.—World production of titanium concentrates (ilmenite and rutile) 1945–51, by countries, in metric tons

Australia.—Nine companies extracted rutile from beach sands in the Byron Bay area on the eastern Australia coast in 1951, 4 of which belonged to the Mineral Sands of Australia Association.[16] Zircon Rutile, Ltd., Byron Bay, New South Wales, announced that its rutile production in 1951 was more than double the quantity produced in 1950, when output was restricted. However, this rutile supply was insufficient to meet the demand, and many overseas orders had to be canceled.[17] Titanium & Zirconium Industries Pty., Ltd., found large low-grade deposits of rutile and ilmenite in the sand dunes of Stradbroke Island. At the end of 1951 this company was testing material obtained from suction dredging in swamp areas, sand dunes, and rich beach concentrates in its pilot plant on the island. Primary concentration was effected by Humphrey spirals. The annual capacity of the plant was 1,500 tons of rutile concentrates.[18]

The Bureau of Mineral Resources at Canberra announced that Australia has the largest known deposits of titanium in the world on the beaches and sand dunes for about 50 miles north and south of the New South Wales-Queensland border. The Zinc Corp. operated a trial plant on Stradbroke Island, Queensland, and expected to begin large-scale production.[19]

Strong American rutile buying for industrial purposes booked Australian producers for 1951 and 1952; however, future markets were uncertain because of generally increased costs of production and the possibility of increased sea freights.[20] Price of rutile in Australia during 1951 fluctuated around 4 cents a pound, on 95 to 97 percent TiO_2, c. i. f. Australia.[21]

Brazil.—The Companhia Quimica Industrial, CIL, South America, began constructing a titanium oxide plant at Engenheiro Trinidade, San Pablo, during 1951. This plant, the first of its kind in Central and South America, was expected to produce for domestic use 20 metric tons of titanium oxide and 50 tons of sulfuric acid per day.[22]

Rutile and ilmenite exports from Brazil to foreign countries totaled 15,426 tons and 20,167 tons, respectively, from 1937 to 1948.[23]

Canada.—Quebec Iron & Titanium Corp., subsidiary of Kennecott Copper Corp. and New Jersey Zinc Co., conducted mining operations on the world's largest ilmenite deposits at Allard Lake, Quebec. The ore in the 100-million long ton Main ore body and in the 12-million ton Cliff ore body averaged 32 percent TiO_2 and 36 percent Fe. Mining in 1951 was confined to the Main ore body, where 25-foot benches expose massive, solid ilmenite faces with very little waste interspersed. The Quebec Iron & Titanium Corp. mined and crushed 342,000 long tons of iron-titanium ore in 1951, during the mining and shipping season that began in April and ended in November. Of this amount, 332,000 tons was shipped from the mine to the smelter by the 550-mile waterway from Havre St. Pierre to Sorel. From initial production in October 1950 to the end of 1951 some 473,000 tons of ore was delivered from the mine to smelter stockpiles.

Ilmenite ore was smelted to produce a titanium-rich slag running about 70 percent or more TiO_2 and an iron product at the Quebec Iron & Titanium Corp. Sorel plant. The electric furnaces at this plant were box-shaped, steel-framed, refractory-lined units containing 6 graphite electrodes in line; 224 and 390 volts of power supplied through Amplidyne controls constantly adjusted the elevation of the graphite electrodes to maintain proper temperature and arc voltage. The capacity of each furnace was 300 long tons of ore per day. This was blended with about 43 tons of coal fed on a continuous basis to produce 132 tons of titanium slag and 96 tons of refined iron per day. Titanium slag was tapped off periodically into a cast-steel slag pot and transferred by crane to a tilting mechanism for further refining. Molten iron was also tapped periodically at a 12-hour-cycle per furnace and transferred from the smelter by a 60-ton ladle and crane to the 60-ton electric arc-type refining furnaces.

From initial operation of the first furnace on an experimental basis in October 1950 to the end of 1951 a total of 46,676 long tons of ore was treated, which yielded 16,555 long tons of iron and 19,446 long tons of titanium slag. Titanium-slag production and shipments in 1951 totaled 17,438 and 7,176 long tons, respectively. Titanium slag was shipped in trial lots during 1951 to the pigment industry, of which the United States received 7,076 long tons and England the remaining 100 tons. No titanium slag was shipped in 1950.

Expenditures in the Q. I. T. project to January 1, 1952, totaled some $34.4 million, including $4.8 million for exploration, development, mine property, and construction at the mine at Allard Lake; $7.7 million for the 27-mile railroad from the mine to Harve St. Pierre Terminal; and $18.6 million for construction and experimental operations at the smelter at Sorel.[24]

A surface showing of ilmenite was staked in the St. Adele-St. Agathe district about 50 miles northeast of Montreal. Widths of up to 250 feet were noted, and the assays of two samples taken from the find showed 21 and 12 percent TiO_2, respectively, with iron contents of 48 and 23 percent.[25]

Another recent discovery of titanium-bearing ore was reported in 1951 at Ivry, Canada, north of Montreal. The Ivry deposit contains approximately 1 million long tons of titanium-bearing ore.[26]

Ceylon.—The Government of Ceylon planned a beach mineral plant in 1951 for refining beach mineral sands. Extensive deposits of ilmenite, rutile, and zircon were found at Pulmodai on the northeast coast of Ceylon. The chief product of the plant will be ilmenite, with appreciable amounts of rutile and zircon as byproducts.[27]

India.—A new metallurgical laboratory was completed during 1951 in Jamshedpur upon 26 acres of land donated by Tata Industries, Ltd. Financial assistance for the construction of this laboratory was given by the Indian Government, Sir Ratan Tata Trust, Sardar Bahadur Sir Indra Singh, and others. The working functions of the laboratory include fundamental and applied metallurgical research on titanium ores, minerals, and refractories. Statistical studies,

chemical analysis, physics, the treatment of ores and alloys, metal structure, processing, electrodeposition, and corrosion are a few of the subjects the laboratory intends to cover.[28]

The Government of India fixed an annual overall quota for rutile exports in 1951. The issue of rutile licenses was considered by the Deputy Chief Controller of Exports, Custom House, Madras, India, on receipt of applications supported by a no-objection certificate from the Travancore-Cochin Government, a certificate from the Director of Geology to the effect that the consignment of rutile exported was free from monazite, and a treasury chalan in proof of payment of the appropriate application fees.[29]

Extensive deposits of high-quality ilmenite sands containing up to 50 percent titanium dioxide were found in Ratnagiri district, Bombay. Exploitation of the ore was to begin in the coastal village of Malgund, about 300 miles south of Bombay, at the rate of about 1,500 long tons per year, production to increase up to 5,000 tons. India produced 143,174 metric tons of ilmenite in 1951, most of which was mined in the southwest coastal State of Travancore.[30]

Japan.—The Osaka Special Steel Co. produced charcoal pig iron and titanium slag containing 50 percent TiO_2 by processing iron sands in an electric furnace. A laboratory method for producing metallic titanium from slag was announced by this company in 1951, with the following basic operations: (1) Reduction of iron sand in an electric furnace producing charcoal pig iron and titanium-bearing slag; (2) chlorination of slag, producing titanium tetrachloride; (3) purification of the titanium tetrachloride; (4) reduction of the titanium tetrachloride with magnesium and vacuum distillation to produce metallic titanium.[31]

The estimated ore reserves in the beach sands of Japan totaled about 10 million long tons, averaging 30 to 35 percent Fe and 5 to 10 percent TiO_2. These sands were concentrated in a Mitsubishi wet magnetic separator equipped with a permanent magnet. The concentrates ran about 55 percent Fe, 12 percent TiO_2, and 0.2 to 0.3 percent V_2O_5.[32]

The Nittetsu Mining Co. treated beach sands and obtained about 1,200 tons of concentrates monthly. At another location on the coast of Japan the Misawa Steel Co. produced about 3,000 tons of black sand per month, averaging 35 percent iron and 8 percent titanium oxide. The Kawaaki Steel Co. also recovered black sands. All work of excavating the black sands was done by hand and portable log washers.[33]

Norway.—The only producer of ilmenite in Norway in 1951 was the Sokndal mine on the southwestern coast between Egersund and Flekkefjord. The ore, which contained 17 percent TiO_2 and 20 percent Fe, was concentrated by magnetic separation to an ilmenite concentrate that contained 44 percent TiO_2 and 36 percent Fe and a magnetic

Digitized by Google

concentrate that contained 66 percent Fe and 3 percent TiO_2. The annual capacity of the plant was reported in 1951 to be 100,000 long tons of ilmenite concentrate and 20,000 tons of magnetite concentrate. The deposit covers 75,000 square meters. Reserves to a depth of 100 meters below the present main level in the mine were calculated at 30 million tons of ore averaging 17 percent TiO_2.[34]

Union of South Africa.—A survey report by the Titanium Corp. of South Africa, Ltd., on the Umgababa area of Natal stated that there were 2,000,000 long tons of ilmenite ore containing 48 to 52 percent TiO_2, 200,000 tons of zircon, and 100,000 tons of rutile containing 94 to 97 percent TiO_1 in the claim area. This corporation intended to mine and export these minerals and also erect a pilot plant for the manufacture of titanium dioxide pigments. The Umgababa area reportedly presented no technical difficulties in transportation or electrical facilities, as railroads, highways, sealanes, and power lines are nearby.[35]

Deposits of ilmenite sand were reported at Natal, Swakopmund, and Bushveld Complex and smaller deposits containing 9 to 25 percent TiO_2 in the Tugela Valley below the Middle Duft in Zuzuland. An analysis of the Natal Coast sands indicated that ilmenite makes up 70 to 85 percent of the heavy minerals present, which ranged from 5 to 90 percent. The reserves of these ilmenite coastal sands were very large; however, some large areas were unworkable owing to town-land restrictions and high cost of land associated with seaside resorts. Random sampling of Swakopmund ilmenite sands along the West Coast indicated that heavy minerals ranged from 4 to 87 percent of the sand. Possible utilization of South African titanium resources, location and nature of titanium deposits, methods of processing titanium ore, metallurgical developments, and 60 references on titanium were reported in 1951.[36]

United Kingdom.—The Imperial Chemical Industries, Ltd., in 1951 led all British titanium metal producers so far as being able to offer titanium metal commercially. Work on titanium sponge was done at Widnes, whereas ingot and wrought forms were produced at Witton. Annual output was reported to be about 11 long tons, the bulk of which was absorbed by aircraft engine manufacturers. The price of titanium sponge was quoted in 1951 as about 50/d. ($7.00) per pound, ingot at £5 ($14.00) per pound, and products around £6 ($16.80) and upward.[37]

The British Titan Products, Ltd., manufacturer of titanium oxide pigments, maintains plants at Billingham County, Durham, and at Grimsby. The Billingham plant, originally planned for production of 2,000 tons of anatase-type titanium oxide per year, increased its annual production in 1951 to 16,000 tons per year. The Grimsby plant, completed in January 1949, received permission in April 1950 to double its production capacity of rutile-type titanium oxide from 12,000 to 24,000 tons per year. It was anticipated that at the end of

[34] Bureau of Mines, Mineral Trade Notes: Vol. 33, No. 2, August 1951, p. 24.

Digitized by Google

1952 total anatase- and rutile-type titanium oxide production by this company would be about 40,000 tons per year. This expansion to the existing Grimsby plant was expected to be completed by the middle of 1952 at a cost of more than £1,500,000 ($4,200,000). The cost will include a 140-ton-per-day acid plant operating on pyrites, and it will incorporate the first flash roaster unit in the country.[38]

Prices of titanium pigments increased in February 1951 for the first time in 2 years, principally because of increased manufacturing and raw-material costs. In July 1951 the new basic price of rutile-type titanium oxide was £133 ($372.40) per ton, and the anatase type £115 ($322.00) per ton.[39]

Changes in United Kingdom tariff laws were made in September 1951 as a consequence of the tariff concessions agreed upon by the United Kingdom during the conference at Torquay, allowing the titanium dioxide rate of duty to drop to 15 percent from the previous rate of 20 percent. This rate was chargeable on and after September 1, 1951.[40]

Western Germany.—Titangesellschaft, m. b. H. reported the construction of an additional production unit to its titanium dioxide plant at Leverkusen, West Germany. War damage that destroyed 80 percent of the prewar capacity at this plant was repaired in the latter part of 1949; however, 1951 output of titanium dioxide pigment was not sufficient to meet domestic demand. Therefore, titanium dioxide was not available for export in 1951.[41]

Tungsten

By Robert W. Geehan and Charles Katlin

GENERAL SUMMARY

DURING 1951 production of tungsten concentrates reached the highest level since 1944, and consumption exceeded all years since 1945. The first half of 1951 was a critical period, with consumption exceeding production and imports; however, during the latter half of the year the import rate increased materially, and drawdown of inventories as a means to cover excess consumption was no longer necessary. The Government instituted drastic restrictions on the use of tungsten, provided a long-term program designed to stimulate domestic production, and began to purchase foreign concentrates for resale to industry. The price of tungsten concentrates increased. In April the domestic ceiling price was set at $65 per short-ton unit,[1] but foreign prices reached levels well above this point.

TABLE 1.—Salient statistics of tungsten concentrates in the United States,[1] 1947–51, in pounds of contained tungsten

Year	Production	Shipments from mines	Imports for consumption	Consumption	Industry stocks at end of year		
					Producers	Consumers and dealers	Total
1947	3,026,470	2,944,622	6,018,005	7,812,000	368,316	3,343,392	3,711,708
1948	4,033,389	3,838,287	7,648,101	8,853,000	563,418	5,284,901	5,848,319
1949	2,896,084	2,631,506	6,274,102	4,958,000	827,045	4,229,444	5,056,489
1950	3,965,040	4,587,687	16,147,313	6,597,000	216,468	5,121,206	5,337,674
1951	5,913,750	5,972,551	6,376,513	11,410,000	234,282	4,037,502	4,271,784

[1] Includes Alaska.

Domestic production increased 49 percent over 1950. California was again the leading tungsten-producing State, followed by Nevada and North Carolina. The Pine Creek mine of United States Vanadium Co. retained first place among United States producers of tungsten.

General imports and imports for consumption were both less in 1951 than in 1950. Noteworthy were the decrease in shipments (general imports) from Korea from 2,345,000 pounds (metal content) in 1950 to 905,000 pounds in 1951 and the increase in shipments from Spain and Portugal from 136,000 pounds (metal content) in 1950 to 1,816,000 pounds. General imports were well below average during the first half of 1951; and in February amounted to only 228,000 pounds (metal content) as contrasted with the average monthly receipt of 628,000 pounds for the year.

[1] A short-ton unit equals 20 pounds of tungsten trioxide (WO_3) and contains 15.862 pounds of tungsten (W). A short ton of 60-percent WO_3 contains 951.72 pounds of tungsten

Digitized by Google

Consumption of concentrates (60-percent WO_3 basis) in the United States was 11,989 short tons in 1951, compared with 6,932 tons in 1950. The trend toward increased use of tungsten carbide and other products produced from tungsten metal powder continued in 1951.

Industry stocks of tungsten concentrates (60-percent WO_3 basis) were 4,488 short tons on December 31, 1951, compared with 5,608 tons at the end of 1950.

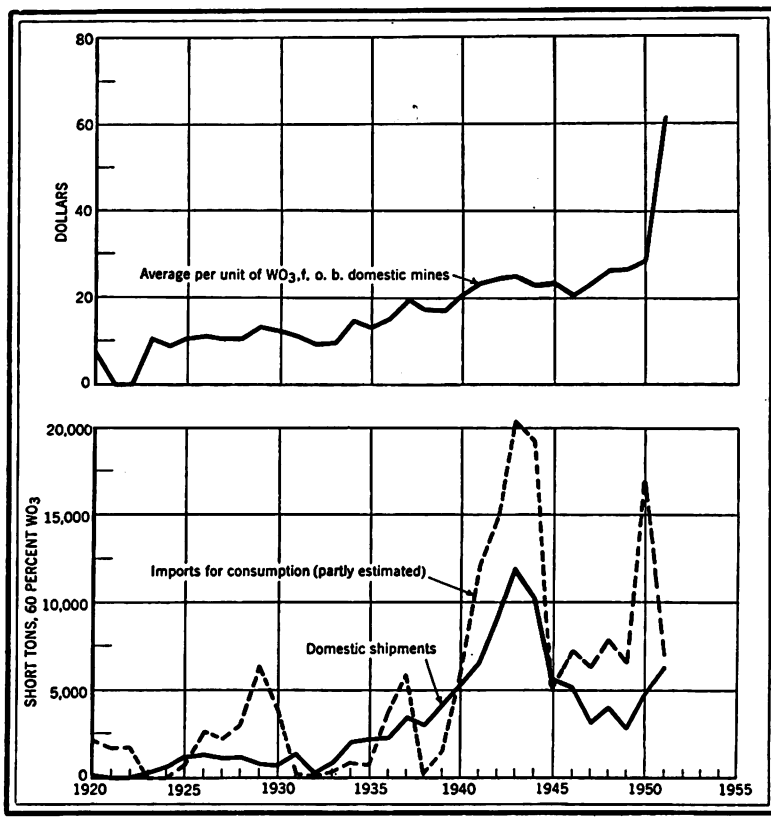

FIGURE 1.—Domestic shipments, imports, and average price of tungsten ores and concentrates, 1920–51.

GOVERNMENT REGULATIONS

To stimulate domestic production, General Services Administration announced a domestic tungsten program to be carried out in accordance with a policy determination made by Defense Minerals Administration and Defense Production Administration. The original program announced May 10, 1951, provided for the purchase of standard-grade tungsten concentrates by the Government at $63 per short-ton unit for 5 years or until 1,468,750 units were purchased. On June 20, 1951, it was amended to provide for termination of the

Digitized by Google

program when 3,000,000 short-ton units had been delivered or on July 1, 1956, whichever occurred first. The program contained a penalty schedule which outlined deductions from the base price of $63 for offgrade concentrates. On December 27, 1951, the schedule was modified to provide a higher allowance for molybdenum without penalty.

Defense Minerals Administration issued Orders MO–4 and MO–6 regarding the allocation of tungsten concentrates. The National Production Authority issued Orders M–30, M–80, and M–81 covering allocation and use of tungsten products. The Office of Price Stabilization announced several orders affecting tungsten; among these are GCPR–SR 42, CPR–19, CPR–33, and GOR–9. At the end of 1951 the following ceiling prices were in effect:

Tungsten concentrates, $65 per short-ton unit.
Ferrotungsten, $5 per pound of contained tungsten (in lots of 10,000 pounds or more).
Carbon-reduced tungsten metal powder, $6 per pound.
Hydrogen-reduced tungsten powder, $7.75 per pound.
Tungstic acid, $4.30 per pound (in 1,000-pound lots).
Tungstic oxide, $4.65 per pound (in 1,000-pound lots).
Ammonium paratungstate, $4.15 per pound (in 1,000-pound lots).
Sodium tungstate crystals, $3.15 per pound (in 250-pound lots).
Anhydrous sodium tungstate, $3.55 per pound (in 255-pound lots).

The International Materials Conference was established early in 1951 to cope with international problems relating to scarce materials. A Tungsten-Molybdenum Committee was formed. This committee announced agreements regarding tungsten that had been approved by the member Governments. During the third quarter all member producing and consuming nations, except Brazil, agreed that producing nations would not demand a price higher than $65 per short-ton unit and that importing nations would pay at least $55 f. o. b. port of shipment. There was no similar agreement during the fourth quarter. For the third and fourth quarters, international quotas were announced; the United States was allotted 44.8 and 47.8 percent, respectively, of the estimated free world production.

DOMESTIC PRODUCTION

The tungsten ore mined and milled in the United States, in general, contains 0.3 to 2.5 percent WO_3 and is usually beneficiated to a concentrate containing 60 percent or more WO_3. The leading tungsten producers in the Western States depend on ore containing tungsten only as scheelite (calcium tungstate). Hübnerite (manganese tungstate) is the chief tungsten mineral in ores produced in North Carolina and is also important in Idaho and Colorado deposits. Wolframite (iron-manganese tungstate) and ferberite (iron tungstate) contributed only minor quantities of the tungsten ore mined in 1951. Some concentrates are treated by chemical processes to remove impurities; still others are dissolved and reprecipitated as synthetic scheelite. Most of the concentrates are then shipped to plants for conversion to ferrotungsten or tungsten powder. However, some high-purity scheelite concentrates are sent to steel plants, where they are charged directly to the steel bath.

802512—54——82

Digitized by Google

During 1951 many producers expanded the capacity of mines and surface plants, and output of concentrates (60 percent WO_3 basis) increased to 6,214 tons in 1951 compared with 4,166 tons in 1950.

TABLE 2.—Tungsten concentrates produced and shipped in the United States, 1950–51, by States [1]

State	Produced				Shipped from mines

[1] Includes Alaska.
[2] Values apply to finished concentrates.

Production in 1951 was obtained from many widely scattered operations in 9 States and Alaska, but 3 States—California, Nevada, and North Carolina—supplied 88 percent of the total; and 8 operators—Bradley Mining Co., Climax Molybdenum Co., Getchell Mine, Inc., Nevada-Massachusetts Co., Nevada Scheelite, Inc., Surcease Mining Co., Tungsten Mining Corp., and United States Vanadium Co.—produced 87 percent of the United States total. California was again the premier tungsten-producing State, and Nevada the second largest.

Digitized by Google

Alaska.—Rocky Mountain Mining Co. (near Nome), Russell R. Schaefer (Crooked Creek), and United States Tin Co. (Lost River) produced small quantities of tungsten concentrates.

Arizona.—There was a marked increase in activity at tungsten deposits in Arizona during 1951; reports indicate 18 operators as contrasted with only 2 in 1950.

George W. Campbell & Sons produced 2 tons of concentrates from the Blue Eagle claims in Yuma County. L. G. Fernstrom & Co. reported the construction of a 25-ton mill and production of 1.5 tons of concentrates from Las Guijas mine in Pima County. An output of 2 tons of concentrates came from the J. F. Moore mine in Mohave County. Nikas Mining Co. mined 600 tons of ore from the Morning Star mine; much of this was shipped to a custom mill. K. Short reported production from the Boriana deposit in Mohave County.

TABLE 4.—Tungsten concentrates shipped from mines in the United States, 1946–51, shipments for maximum year, and total shipments, 1900–51, by States, in short tons of 60 percent WO_3[1]

State	Maximum shipments		Shipments by years							Total shipments, 1900–51

Total	1943	11,945	5,193	3,094	4,033	2,765	4,820	6,275	100.00	136,947	100.00

[1] Shipments are credited to the State where final concentrates were produced.
[2] Less than 0.5 ton.
[3] Less than 0.01 percent.

California.—With a 48-percent increase in output, California again was the major tungsten-producing State. Production in 1951 was 2,208 short tons of concentrates averaging 68 percent WO_3, compared with 1,468 tons averaging 69 percent WO_3 in 1950. Shipment of concentrates totaled 2,590 short tons averaging 70 percent WO_3, compared with 1,751 tons averaging 69 percent WO_3 in 1950. Concentrates produced at Pine Creek from ores and low-grade concentrates produced in other States are not included in the California production but are included in shipments. Of the 119 tungsten producers in the State, 5 (Black Rock Mining Corp., Fresno Mining Corp., Mineral Materials Co., Surcease Mining Co., and United States Vanadium Co.) supplied 92 percent of the total production. Other important

Digitized by Google

producers were Don Burgner, Consolidated Tungsten Mine, Garnet Dike Mine, Hanging Valley Tungsten Co., Huntley Industrial Minerals, Inc., R. D. Morris, Sherman Peak Mining Co., and Tulare County Tungsten Mines.

The United States Vanadium Co. Pine Creek mine and concentrator near Bishop again was the leading producer of tungsten concentrates in the United States in 1951 and also treated a large quantity of ore and concentrates produced by other firms. Total production of concentrates was 74 percent higher than in 1950, while the output of the Pine Creek mine increased 25 percent. Mine development during 1951 included driving 2,700 feet of raises and 2,300 feet of drifts and crosscuts. The company completed a separate crushing, conveying, and sampling plant, with a capacity of 1,000 tons in 8 hours, to treat custom ores.[2]

Black Rock Mining Corp. resumed operations at the Black Rock mine near Bishop from which it mined 42,287 short tons of tungsten ore which was shipped to the United States Vanadium Co. concentrator nearby.

Surcease Mining Co. produced 194 short tons of concentrates at its plant near Atolia, a 14-percent increase over its 1950 total. The Star Bright mine, operated by Mineral Materials Co., produced 105 tons of concentrates, a 134-percent increase over the 1950 output.

Fresno Mining Co. increased production of concentrates during 1951 at the Strawberry mine near Fresno to 90 short tons. A new flotation unit was installed to treat tailings, and new ore bodies were being developed in the No. 4 mine. The Garnet Dike mine, also near Fresno, increased its output of tungsten concentrates by 80 percent over the 1950 quantity. The Alpine mine in Alpine County, idle in 1950, mined and treated 2,225 tons of ore during 1951 under the operation of R. D. Morris. The Shamrock mine in Inyo County was a new producer.

Consolidated Tungsten mine, a division of Kennametal, Inc., operated the Harrel Hill mine in Tulare County. The Hanging Valley Tungsten Co. reported production of 12 tons of concentrates in a 2-month operative period at the Hanging Valley mine near Bishop in 1951; during 1950 this mine was idle. Development at this deposit in 1951 included driving a new 120-foot adit.

Huntley Industrial Minerals, Inc., extracted 10 tons of concentrates from ore and tailings at the Huntley mines near Bishop; the mine was not worked during 1950. Production more than double the 1950 output was achieved by the Sherman Peak Mining Co. from the Sherman Peak and Hill Top mines. Tulare County Tungsten Mines production from the Big Jim mine in 1951 was 16 tons of concentrates; the mine was core drilled during 1951. A 50-ton mill was installed by the Good Hope Mining Co. at the Pioneer mines and Good Hope claim in Tulare County, Calif.

Colorado.—Tungsten concentrates produced and shipped in 1951 totaled 317 short tons averaging 62 percent WO_3, and 322 tons averaging 63 percent WO_3, respectively; 1950 production and shipments were 176 tons averaging 67 percent. There were 41 producers of tungsten in Colorado in 1951, but only 5 produced over 6 tons of concentrates.

[2] McKinley, H. L., Holmes, T. W., and Sausa, L. E., How U. S. V.'s Pine Creek Mine Will Increase Tungsten Output: Eng. and Min. Jour., vol. 152, No. 5, May 1951, pp. 76-83.

Digitized by Google

The byproduct plant of the Climax Molybdenum Co. at Climax, Lake County, designed to recover valuable minerals occurring in minute amounts in the molybdenite ore treated contributed the major portion of Colorado's production of tungsten concentrates in 1951. The following data have been abstracted from the firm's Annual Report for the year 1951:

During the year 1951 the company produced approximately 259,000 pounds of tungsten contained in the form of concentrate. This compared with 162,000 pounds during 1950. Research to improve recoveries of tungsten has been moderately successful and will be continued. The combination of greater capacity and improved recoveries should result in substantially increased production during 1952.

There was also a byproduct recovery of pyrite, tin concentrate, monazite, and topaz.

Hetzer Mines, Inc., recovered 24 short tons of concentrates from ferberite ores shipped to its mill near Nederland by lessees of Hetzer Mines properties and others. Johnson Bros. & Prime, operating the Hoosier mine near Nederland, produced 15 tons of concentrates in 1951 and completed 250 feet of drifting during the year on the 225-foot level. Vanadium Corp. of America leased the Hetzer mill in November 1951 and produced some concentrates there during the last 2 months of the year. Cobb and Weldon produced tungsten concentrates from various properties leased from Hetzer Mines, Inc.

Idaho.—In 1951 the Bradley Mining Co. produced 216 tons of hübnerite concentrate from the Ima mine, Lemhi County; this presented an increase of 99 percent over 1950. Considerable scheelite was obtained from its Yellow Pine mine, Valley County, as a byproduct in antimony-gold ore operations and from the Ima mine as a coproduct of the hübnerite.

The McRae Tungsten Corp. drove 150 feet of drift at the Snowbird mine. Small quantities of concentrate were produced by M. W. Hickman & A. W. Kelsey, of Riggins, and by Walter Schmitroth, of Smelterville.

Montana.—The only reported production was the mining of 300 tons of ferberite ore by the Alps Mining & Milling Co. from the Harvey Creek Argo Group mine in Granite County. A small quantity of concentrates was shipped by H. & H. Mines from the Henderson Creek mine in Granite County.

Nevada.—With a 90-percent increase over 1950 in its output of tungsten concentrates, Nevada moved up to the second-place position as a tungsten-producing State in 1951. Shipments totaled 1,271 short tons of tungsten concentrates averaging 70 percent WO_3 compared with 883 tons averaging 76 percent WO_3 the previous year. (Much low-grade concentrate was beneficiated at plants in other States before final shipment.) There were 32 tungsten producers in 1951, but 5 (Gabbs Exploration Co., Getchell Mine, Inc., Lindsay Mining Co., Nevada-Massachusetts Co., and Nevada Scheelite) supplied 95 percent of the total production of tungsten concentrates.

The Nevada-Massachusetts Co. retained first place among Nevada tungsten producers. The company recovered 627 tons of concentrates from its Mill City operations; mining was carried on steadily

Digitized by Google

at the Stank, Humboldt, and Sutton No. 2 underground mines, as well as in open pits. Improvements were made in the crushing plant, and alterations were being effected in the milling plant to increase capacity and efficiency.

Getchell Mine, Inc., idle in 1950, derived the second largest tungsten production in the State during 1951 from 121,000 short tons of ore taken from the Getchell mine near Winnemucca. Toward the end of the year an increasingly efficient flotation operation raised the general grade of the concentrate considerably. The Getchell mill treated 18,800 tons of custom ore. Lindsay Mining Co., operating the Gunmetal mine in Mineral County, produced 61 tons of concentrates and custom-milled a small additional quantity; the mine was idle in 1950.

Gabbs Exploration Co. had a considerable production of tungsten concentrates from the mine of the same name in Nye County. The Nevada Scheelite mine in Mineral County became a division of Kennametal, Inc.; the mine yield of concentrates in 1951 increased 39 percent over the previous year's output. During the year the shaft was sunk an additional 100 feet to the 400-foot level, and drifts were driven from there. A production of 34 tons was obtained from El Capitan mine in Nye County, operated by Gordon Smith. The Stormy Day mine, operated by John B. Mayfield, produced 6 tons of concentrates; developments included a 200-foot exploration tunnel and a 60-foot winze.

Other notable producers of tungsten concentrates were Boundy and Claghorn, of Cherry Creek; Cherry Creek Mining Co. operating the Cherry Creek mine in White Pine County; Minerva Scheelite Mining Co., of Ely; Nevada Tungsten Corp. operating the Silver Dyke mine in Mineral County; and Fred Vollmer.

A considerable quantity of tungsten ore was mined by the Valley View Mining Co. from the mine of the same name near Winnemucca. Nevada Mining Co. operating the Mountain King claim near Red House, Black Rock Mining Co. operating the Lincoln mine in Lincoln County, and Gale G. Peer operating the Conquest mine near Austin also produced sizable quantities of tungsten ore.

North Carolina.—In 1951 the Tungsten Mining Corp., sole tungsten operator in the State, produced 1,145 short tons of tungsten concentrate averaging 54 percent WO_3 from the Hamme mine in Vance County, compared with 1,086 tons averaging about 60 percent WO_3 in 1950. Shipments by the company totaled 1,135 tons averaging 55 percent WO_3 in 1951 as compared with 1,200 tons averaging 62 percent WO_3 in 1950. This firm produces a high-grade hübnerite concentrate along with some low-grade sheelite concentrate that is shipped to another firm for upgrading. During 1951 work included 16,019 feet of drilling and 9,023 feet of development. The Central shaft was deepened 258 feet to the 827-foot level, and the Sneed shaft was sunk from the 500-foot level to 785 feet. The milling plant capacity was being increased to 600 tons.

Utah.—The Beaver Tungsten Mines, Inc., sank 100 feet of shaft at its mine near Beaver. The Desert Tungsten Co. mined a small amount of ore from the Desert mine, Juab County. Small quantities of concentrates were shipped by Star Dust Mines, Inc., of Salt Lake City and D. G. Brush of Delta. Cecil R. Woodman produced a small

Digitized by Google

amount of tungsten concentrates from the Yellow Hammer mine, Tooele County.

Washington.—Germania Consolidated Mines, Inc., reported the production of 12 tons of concentrates, chiefly wolframite, from the Germania Consolidated mine in Stevens County near Fruitland. A small quantity of scheelite concentrate was produced by the Kelly Camp Tungsten Co. from the mine of the same name in Ferry County; new equipment included a ball mill and magnetic separator. Some concentrates were shipped by the Pacific Mining Co. of Spokane. The Tungsten Mining & Milling Co. produced a small amount of concentrates from the Germania mine in Stevens County near Wellpinit.

CONSUMPTION AND USES

Consumption of tungsten concentrates (60-percent WO_3 basis) in the United States was 11,989 short tons in 1951, compared with 6,932 tons in 1950. Of the total consumed in 1951, 2,310 tons (19 percent) was converted into ferrotungsten, the form in which much of the tungsten is introduced into steel. However, high-purity tungsten concentrates are charged directly to the steel bath; 1,300 tons (11 percent) was so used in 1951. Tungsten-metal powder and other tungsten products, chiefly the former, utilized 8,379 tons or 70 percent of the total concentrates consumed in 1951.

Changes in the use pattern of tungsten during the period 1942–51 are indicated in table 5. The increased use for "Metal powder and other" reflects growth in the tungsten carbide industry. Tungsten powder is the raw material from which nearly all tungsten carbide is produced.

TABLE 5.—Consumption of tungsten concentrates in the United States, 1942–51, by uses, in short tons of 60 percent WO_3

Year	Ferrotungsten		Direct to steel		Metal powder and other		Total
	Quantity	Percent of total	Quantity	Percent of total	Quantity	Percent of total	
1942	12,400	68	3,100	17	2,750	15	18,250
1943	12,300	61	2,900	14	5,100	25	20,300
1944	11,800	59	2,600	13	5,700	28	20,100
1945	7,400	50	2,000	13	5,500	37	14,900
1946	2,400	35	1,900	28	2,500	37	6,800
1947	3,800	46	1,400	17	3,000	37	8,200
1948	4,100	44	1,850	20	3,350	36	9,300
1949	2,472	47	838	16	1,900	37	5,210
1950	1,165	17	1,966	28	3,801	55	6,932
1951	2,310	19	1,300	11	8,379	70	11,989

PRICES

Late in January the General Ceiling Price Regulation was announced; this led to several sets of ceiling prices, depending on the dates of previous shipments. On April 6 a uniform ceiling price of $65 per short-ton unit was established; this was modified on May 1 by an announcement that tungsten concentrates of foreign origin were freed of price control when sold to any agency of the United States Government. Quotations listed in E&MJ Metal and Mineral Markets were $56.50 per short-ton unit at the start of the year and

Digitized by Google

$65 after February 1 for domestic concentrates, f. o. b. North Carolina. No quotations were published for western concentrates until April 6; after that date all domestic concentrates were listed at $65. Similar quotations for foreign concentrates (London prices) ranged from $50 at the start of the year to $78.75 on March 15, fluctuated in the range $65–$73 to July 19, held steady at $67 until December 20, and closed the year at $64.50 (all prices per short-ton unit, without duty). After the duty of $7.93 per short-ton unit is added to the foreign quotations, it is evident that no foreign tungsten could be imported at or below the ceiling price of $65 per short-ton unit after the April 6 date, when this ceiling price was announced. This situation prevented imports for consumption by private firms and led to sales to industry, at the ceiling price, of material imported by the Government.

As reported to the Bureau of Mines, the average price for domestic concentrates shipped was $61.02 a short-ton unit in 1951.

FOREIGN TRADE [3]

Domestic production is inadequate for requirements, and the United States imports both tungsten concentrates and products, chiefly the former. In 1951, the movement of tungsten concentrates from foreign sources to the United States was disrupted by factors discussed in the previous section. During the first 4 months of 1951 general imports averaged only 410,433 pounds, tungsten content, per month, and in February they were only 227,988 pounds; the average for 1950 was 695,166 pounds. Action by the Government, which included purchases of foreign tungsten concentrates for resale to industry and participation in the International Materials Conference, coupled with increased world production, reversed this trend, and average monthly general imports for the last 8 months of 1951 were 736,539 pounds.

In 1951 Portugal replaced Korea as the main source of imports of tungsten in ores and concentrates and contributed 1,280,000 pounds (general imports), as compared with 131,000 pounds in 1950; Korea dropped from first place to fourth and contributed 905,000 pounds in 1951, compared with 2,345,000 pounds in 1950. China, the most important source in many prior years, contributed only 34,000 pounds; this contrasts with 4,960,000 pounds in 1949.

Imports for consumption of tungsten metal, chiefly from United Kingdom, were 85,086 pounds (210,972 pounds in 1950). Imports for consumption of ferrotungsten, chiefly from Japan, were 2,018,035 pounds (gross weight) containing 1,574,187 pounds of tungsten (1,379,979 pounds tungsten content in 1950). Imports of tungstic acid, chiefly from Japan, contained 2,810 pounds of tungsten. Imports of ferrochromium tungsten contained 114 pounds of tungsten.

In 1951, there were reexports of 16 tons (gross weight) of tungsten ore and concentrate and no exports, compared with 328 and 7 tons, respectively, in 1950. Exports of ferrotungsten were 283,701 pounds (gross weight) in 1951 (332,705 pounds in 1950). Exports of tungsten metal, stellite, wire, shapes, and alloys other than ferrotungsten were 248,054 pounds (gross weight) in 1951 (151,968 pounds in 1950).

[3] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

[1] Includes ores and concentrates imported for immediate consumption plus material entering country under bond.

[2] Includes ores and concentrates withdrawn from bond during year (irrespective of time of importation) plus imports during year for immediate consumption. This includes imports which entered duty free for the United States Government.

WORLD REVIEW

Continued large demand and attendant high prices accounted for a 28-percent rise in world production over 1950. At the end of 1951 several large deposits were being prepared for production. High export duties and rigid Government regulations regarding foreign exchange continued to retard production. However, late in 1951 satisfactory arrangements to counteract these restrictions were being worked out.

Digitized by Google

Algeria.—Underground development was reported to have blocked out 52,000 metric tons of ore with an average grade of 1.4 percent WO_3 at Beneleta near Bone in northeastern Algeria. A mill was being erected at the deposit.[4]

Argentina.—Argentina, which had a large production during World War II, had a very small output in 1951 and shipped only 17 pounds of contained tungsten to the United States. Negotiations under way during the year were expected to lead to a resumption of large-scale production.

Australia.—King Island Sheelite, Ltd., mined and milled 163,710 long tons of ore averaging 0.55 percent WO_3 during the year ended October 31, 1951. Production of concentrates totaled 973.06 tons with an average grade of 61.6 percent WO_3 and included 8,000 units from the Vanner retreatment plant. This new retreatment plant was completed in May 1951 and produced concentrates assaying 48.8 percent WO_3. The water shortage of the previous year was avoided by the completion of a 45-million-gallon water storage dam in time to retain the winter rainfall. The firm estimated ore reserves at the end of October 1951 to be 2,465,736 tons.

It was reported that a company was formed to acquire and exploit the Pioneer mine near Hatches Creek, Northern Territory, and that Tungsten Consolidated, Ltd., acquired an option on the reputedly rich deposit at Rye Park near Frogmore, New South Wales.[5]

Bolivia.—A new schedule of compulsory foreign exchange regulations applicable to tungsten exports was established in July.[6] It was expected that loans and long-term purchase agreements which were completed or being negotiated between the United States and major Bolivian producers would lead to development of tungsten mines and to the expansion of milling facilities.

Of the 1,631 metric tons of tungsten concentrates exported from Bolivia in 1951, 1,447 tons was shipped to the United States and the remainder to the United Kingdom. Most of these concentrates were of the wolframite type.

Burma.—Despite the hampering activities of insurgents and Karen revolutionists, Burma produced more tungsten concentrate in 1951 than in any year since 1948.

Canada.—Canadian Exploration, Ltd., the subsidiary of Placer Development, Ltd., resumed operations at the Government-owned Emerald Tungsten mine at Salmo, British Columbia. A 250-ton mill was installed for the Government and operations were begun in November of 1951. A deposit outside the Government-owned area was explored, and the mill was to be expanded to provide capacity for treating ore from this area.[7]

China.—Soviet Russia was reported to have sent 260 technicians to develop tungsten mines in China.[8]

Finland.—In 1951, 6 tons of tungsten concentrates was obtained as a byproduct from 13,363 metric tons of ore produced at the Ylojarvi copper mine.

France.—The tungsten mines in France were described.[9]

Hong Kong.—Output of the Needle Hill mine, the only licensed tungsten mine operating in the colony during 1951, was 19 tons of tungsten concentrate. Shipments during 1951 were 15 tons to the United Kingdom and 4 tons to the United States.

India.—Wolframite mining was reported to have been resumed at the mines at Digana, Jodhpur State, Rajasthan, after 5 years of inactivity.[10]

Korea.—In spite of the fighting in Korea, a relatively small output of tungsten was maintained during 1951. Flotation tests on ore from the San Dong mine, from which most of this production was obtained, were described.[11]

Mexico.—The Mesa Larga tungsten mine in Chihuahua was worked as a placer and vein deposit. Production from June 1950 to June 1951 was reported to total 350 to 400 metric tons of concentrates.[12]

Portugal.—Agreements were signed by three Portuguese companies (Minas de Cerva, S. A. R. L., Sociedade das Minas do Gerez, Lda., and Miniera Gouveense, Lda.), with ECA, which was to provide the necessary equipment to expand production.[13]

The export duty on tungsten concentrates was increased in June 1951 to 40 escudos (about $1.40) per kilo (2.2 pounds) from the previous level of 1½ escudos per kilo. Production of tungsten in Portugal during 1951 nearly doubled that of 1950.

Southern Rhodesia.—Equipment was installed to recover scheelite from the gold ore milled at the Sunace mine of Falcon Mines, Ltd.[14]

A fourfold increase in production over that of 1950 was obtained in Southern Rhodesia in 1951.

Spain.—Production of concentrates increased from 850 metric tons in 1950 to 2,300 in 1951. Much of the increase was the output of "Aventureros," men who mine by hand methods wherever ore is available. The Carmen mine in La Coruna Province was an important producer. New exchange rates were established for the export of tungsten.[15]

Thailand.—A contract was signed by the United States Government and the Mae Lama Co. calling for the delivery of 2,000 long tons of concentrates during the 3-year period 1952–54.[16]

United Kingdom.—Small-scale mining of tungsten ore was resumed in Devonshire.[17]

Uganda.—Mining and milling equipment was replacing primitive hand methods in Uganda during 1951.[18]

Uranium, Radium, and Thorium

By H. D. Keiser

GENERAL SUMMARY

EXPANSION of the Nation's atomic energy program proceeded in 1951 at an accelerated pace marked by intensive activity in all phases of the program; plans for further expansion were formulated beyond that authorized by the Congress under the $2,032 million appropriated for the fiscal year ended June 30, 1951. Atomic weapons were produced at the rate authorized by the President for the year 1951, and significant advances were made in weapons research and development.

New construction announced by the Atomic Energy Commission in 1951 included a $54 million feed materials plant at Fernald, Ohio, and a $45 million production plant near Denver, Colo. Construction was in progress throughout the year on the $1,250 million Savannah River Project (the so-called hydrogen or superbomb project) in Aiken and Barnwell Counties, S. C., and on the $500 million gaseous diffusion plant at the Kentucky Ordnance Works near Paducah, Ky.

Production of the fissionable isotope uranium–235 and plutonium in 1951 were at a new record rate and at lowered unit costs despite higher labor and material costs. Output of domestic uranium ore reached a record-breaking level as the result of a well-stimulated raw materials program. Two new ore-processing mills, to treat the increasing quantities of ore, were placed in operation during 1951—one at Salt Lake City, Utah, and the other at Grand Junction, Colo. Deliveries of uranium ore from the Belgian Congo and Canada continued at scheduled rates, and plants were under construction in the Union of South Africa for recovering uranium to be sold to the United States and the United Kingdom. Shipments of radioisotopes by the AEC in 1951 were 26 percent larger in number than in 1950.

MINE AND MILL PRODUCTION

Increased productive activity in 1951 resulted in the United States maintaining its position as second among the free nations in the mining and processing of uranium ores.[1] The record-breaking domestic production was attributable to an expanded exploratory drilling program, higher prices for uranium ores (*see* section on Prices), a bonus for initial ore production, the opening of new producing areas, and increased processing capacity.[2] Over $250,000 was paid in 1951 to ore producers by the AEC under the new bonus program,[3] and about

the same amount was involved under the seven uranium-exploration contracts executed by the Defense Minerals Administration during 1951.

Virtually all the uranium ore mined in 1951 came from the Colorado Plateau, where exploratory drilling by the AEC and the Geological Survey reached a combined rate of nearly 750,000 feet a year, almost double that for 1950. Two new ore-processing plants were placed in operation during 1951—one by Vitro Chemical Co. at Salt Lake City, Utah, and the other by Climax Uranium Co. at Grand Junction, Colo. A detailed description was published of the plant operated by the Galigher Co. (for the AEC) at Monticello, Utah.[4] Toward the close of 1951 negotiations were concluded with the Anaconda Copper Mining Co. for constructing an ore-buying station and a processing plant in the Grants, N. Mex., district.

A significant area of activity in 1951 was the Marysvale, Utah, district, where five mines in the central area produced substantial quantities of ore. In the Grants, N. Mex., district intensive exploration was continued by the Atchison, Topeka & Santa Fe Railway Co. on its holdings, and important reserves of carnotite were delineated in the Todilto limestone. The Anaconda Copper Mining Co. entered the Grants, N. Mex., district early in 1951 and pursued an extensive exploration program; the company was designated by the Laguna Indian Tribal Council to carry out a detailed exploration program on the tribal lands east of Grants. Copper-uranium ore was mined during 1951 in the White Canyon area of southeastern Utah.

Carnotite deposits were discovered in 1951 near Edgemont, S. Dak., in the Lakota member of the Dakota sandstone formation; the discovery indicated carnotite deposition over a broad area in the Dakotas, Wyoming, and Montana.[5] Details of the AEC exploration program were presented in the course of several addresses made by representatives of the Commission.[6]

The survey of domestic thorium resources by the Bureau of Mines, under AEC sponsorship, was continued in 1951 and involved investigation of the monazite content of placer deposits in Idaho, Montana, Wyoming, North Carolina, and South Carolina. In examination of several of the southeastern deposits the Geological Survey collaborated with the Bureau.

Consideration was given in 1951 to low concentrations of uranium in carbonaceous and bituminous shales, particularly the Chattanooga formation reportedly found in vast tonnages over thousands of square miles of Tennessee and Kentucky and containing about 0.008 percent U_3O_8.[7] The view was expressed, however, that recovery of uranium from shales was not commercially feasible at present.[8]

Exploration by airborne methods, employing principally the scintillation counter, increased in 1951. About 10,000 miles of airborne radioactivity traverse was flown in 1951 by the Geological Survey,[9] and a magnetometer survey in the Marysvale, Utah, area aided in the exploration for pitchblende.[10]

Development of a process whereby uranium in phosphates can be extracted economically in the production of triple superphosphate was disclosed by the AEC in February 1951;[11] in April 1951 International Minerals & Chemical Corp. announced that it would build a new $10 million phosphate chemical plant at Mulberry, Fla., incorporating a uranium-recovery unit;[12] and in November 1951 construction by Blockson Chemical Co., Joliet, Ill., of the first full-scale plant for recovering uranium from wet-process phosphoric acid was announced. Other companies actively interested in recovering uranium from phosphate were said to include Allied Chemical & Dye Corp., Tennessee Corp., Mathieson Chemical Corp., Armour Fertilizer Works, and Virginia-Carolina Chemical Corp.[13]

REFINERY AND REACTOR PRODUCTION

Uranium.—Output of the fissionable isotope uranium–235 continued to increase in 1951, and unit costs continued to decrease. The unit-cost reductions were made in spite of increasing labor and material costs and resulted from the continuing improvement in production processes and the expanded volume of operations.[14] New construction announced by the AEC in 1951 included a feed-materials plant to be built at an estimated cost of $54 million on a 1,200-acre site at Fernald, Ohio, 19 miles northwest of Cincinnati;[15] a production plant of an undisclosed type to be erected on a 2,500-acre tract near Denver, Colo., to cost about $45 million, and to be known as the Rocky Flats Plant;[16] and another production plant on 4,000 acres at the Pantex Ordnance Works, 17 miles southeast of Amarillo, Tex.[17] Construction proceeded throughout 1951 on the Savannah River Project in Aiken and Barnwell Counties, S. C., reestimated to cost more than $1,250 million, and on the $500 million gaseous diffusion plant at the Kentucky Ordnance Works, near Paducah, Ky. The K–31 addition to the gaseous diffusion plant at Oak Ridge was completed during 1951.[18]

Plutonium.—Production of plutonium in 1951 was also at a new record rate and at new low unit costs. The cost of production was reported to be half of what it was in 1946 and 1947.[19]

[1] Shipped by Manhattan District, Corps of Engineers, U. S. Army Service Forces.

Isotopes.—Midyear 1951 marked the close of the first 5 years' distribution of reactor-produced radioisotopes by the AEC, during which period over 18,900 shipments were made to over 600 institutions in the United States and about 1,100 shipments to approximately 250 institutions in 31 countries abroad.[20] Thousand-curie sources of gamma radiation made of cobalt–60 or tantalum–182 were made available by the AEC in 1951.[21] In August 1951 Bendix Aviation Corp. and Tracerlab, Inc., arranged with the AEC to conduct studies on the problems of chemical processing of radioisotopes and to determine the desirability of designing, constructing, and operating a nuclear reactor for the production of isotopes.[22] Opportunities for private industry in the production of isotopes were outlined, and the ultimate objective of the AEC was said to be "to work itself out of the isotope business."[23]

Radium.—Production of radium in the United States during 1951 was relatively small and principally salvaged from consumers' wastes. Radium and its derivatives were produced by the Canadian Radium & Uranium Corp., New York, N. Y.

Thorium.—The principal domestic producers of thorium compounds (chiefly nitrate and oxide) in 1951 were Lindsay Light & Chemical Co., West Chicago, Ill.; Maywood Chemical Works, Maywood, N. J.; and Rare Earths, Inc., Paterson, N. J. Commercial production of thorium metal in the United States was relatively small; principal producers were Westinghouse Electric Corp. (Lamp Division), Bloomfield, N. J., and Metal Hydrides, Inc., Beverly, Mass. Thorium-production statistics are not available under the regulations of the Atomic Energy Act of 1946.

CONSUMPTION AND USES

Weapons.—Atomic weapons were produced at the rate authorized by the President for the year 1951, and significant advances were made in weapons research and development.[24] Three separate series of

Digitized by Google

tests were held in connection with weapons development—1 at Eniwetok in the central Pacific and 2 at the Nevada testing grounds near Las Vegas. Knowledge gained in the 1951 tests was incorporated in stockpile weapons.[25] The first of the three series of tests, referred to as limited-scale weapons tests, took place in Nevada during January and February and were the first conducted in continental United states since the original atomic bomb was fired at Alamogordo, N. Mex., in July 1945. In April and May the second series of tests, described as a full-scale test program, was conducted jointly by the AEC and the Department of Defense at Eniwetok. The program was said to have included detonations of sufficient energy yield to confirm estimates as to the effects of weapons several times more powerful than the Hiroshima and Nagasaki weapons.[26] The third series of tests, announced as experimental nuclear detonations, was conducted in Nevada during October and November. Major objectives of the tests were to provide data for weapons development purposes and means for studying various physical effects, such as blast, radiation, and heat. The Department of the Army used the tests for a combat-troop training exercise.[27] The scientific director of the AEC tests was reported to have stated that America's atomic knowledge had virtually doubled in 1951 and that the advance in atomic weapons in the year was almost equal to all the previous developments which followed the first nuclear detonation in 1945.[28]

Industrial Power.—Economic and technical studies of nuclear energy as a possible source of industrial power were continued in 1951;[29] the official view on the subject was expressed by the chairman of the AEC as follows:[30]

> When most of us think of the peaceful promise of atomic energy, I believe we think of power—cheap power to do man's work and to bring light into the dark corners of the world. This, of course, is one of our objectives. I would like to be able to tell you today that we have reached a turning point in the road to this objective similar to the one we have reached in the field of weapons, but I cannot. We are still some years away from having the answers to the questions that will have to be answered before we can estimate with any degree of assurance how far we shall be able to advance toward the goal of cheap atomic power, or which is the best road or roads for us to follow. We are now entering a very critical phase of our work in nuclear reactor development which should give us at least some of these answers.
>
> I say we are entering a critical phase in our progress toward power because of the experimental reactors that are now being built and the studies which are now

being made. In these machines and in the results of these studies will be the answers to many of the problems that today confront us.

When these answers begin to come in, we will have a much better basis than we do now for plotting our course into the future and for making intelligent estimates as to just how far we can go. As you know, there have been many guesses made, some very pessimistic and some spectacularly hopeful. For myself, I would like to reserve final judgment until we have answers to more questions than we do now. I do know this: We are going to have atomic energy power plants, but just how many we will have and what contribution they will make to our economy hinges largely on the factor of cost. To make atomic power worthwhile, we must get the cost of these plants down to where they can compete with coal, gas, oil, and hydroelectric plants. When this will be, and in how many areas it will be true, is something about which today we can only guess. But we *are* going to have atomic power, and we are going to have it first for military use, where developmental costs can be charged to the national security. Later, when we know more, and have gotten this developmental phase out of the way, we can make a better estimate about how far we can go. We are now in that critical period when the answers to our questions are beginning to come in.

In December 1951 the AEC experimental breeder reactor at the Commission's reactor-testing station near Arco, Idaho (*see* Uranium, Radium, and Thorium chapter, Minerals Yearbook, 1950) was brought up to criticality and electrical power generated at a rate exceeding 100 kilowatts. Construction of the materials testing reactor and the land-based prototype submarine thermal reactor at the reactor-testing station and of the submarine intermediate reactor at the Knolls (Schenectady, N. Y.) atomic power laboratory were continued throughout 1951. At Oak Ridge the homogeneous-reactor experiment was brought nearer to completion. Design and development facilities leading toward aircraft propulsion by nuclear energy were established at Lockland, Ohio, under new contractual direction.[31]

Privately financed studies of reactor technology by four industrial groups progressed in 1951, and reports were submitted to the Commission by two of the groups, which reports were under consideration by the Commission. One objective of the studies was to give industry an opportunity to invest private funds in reactors and to build and operate them with profit in proportion to efficiency and improvements. In September 1951 the School of Reactor Technology, operated by the Oak Ridge National Laboratory, graduated its first regular class of 43 engineers. Immediately after graduation of the first class, a second class of 67 students began the 12-month course, which was largely classified.[32]

Isotopes.—The AEC made 7,825 shipments of radioisotopes in 1951, an increase of 26 percent over the 6,234 shipments made in 1950. About half of the radioisotope shipments in 1951 were for use in the field of medical therapy. Industrial applications of radioisotopes, particularly the use of cobalt-60, increased substantially and were discussed in the scientific and technical press.[33] Results were

published in 1951 of a technical and economic survey of present and possible future uses of fission products.[34]

Radium.—The overall use of radium continued to decline in 1951 owing to rapid growth in application of radioisotopes, especially cobalt-60, in both medical therapy and radiography. Consumption of radium as an energy source in luminous paints was at about the level prevailing in 1950. (*See* Uranium, Radium, and Thorium chapter, Minerals Yearbook, 1950, for shipments of primary radium refined in the United States, 1941–48, inclusive; data for subsequent years are not available.)

[1] Shipped by Manhattan District, Corps of Engineers, U. S. Army Service Forces.
[2] Metallurgical use included with "Industrial research."
[3] Specific field of utilization unknown (issuance of general authorizations permits approved applicant to use radioisotopes at a specified location for any research and development activity, and permits him to obtain from any supplier any available form and quantity of any radioisotope distributed on authorization or approval of the U. S. Atomic Energy Commission).

PRICES

Uranium Ore.—On February 28, 1951, the AEC announced a new bonus for domestic uranium-ore production and a price increase for Colorado Plateau ores, with the objective of further stimulating the mining of uranium in the United States. The bonus plan, effective March 1, 1951, through February 28, 1954, provided for the following: [35]

1. For new mining properties, bonus payments will be made on each pound of uranium oxide in acceptable ore delivered to qualified mills or Commission ore-buying stations up to and including the first 10,000 pounds.
2. For mining properties that have produced less than 10,000 pounds of uranium oxide during the period April 9, 1948, to March 1, 1951, bonus payments will be made on the difference between what the mining property has delivered between April 9, 1948, and March 1, 1951, and 10,000 pounds.
3. Bonus payments per pound of uranium oxide in acceptable ores produced from qualified mining properties will range from $1.50 for those ores assaying 0.10 percent uranium oxide to $3.50 for ores assaying 0.20 percent or more. Thus, the maximum bonus that may be obtained for production from new mines will range from $15,000 to $35,000, depending on the grade of ore delivered.

The following mills were listed by the AEC as "qualified" uranium mills:
United States Vanadium Co., Uravan, Colo.
United States Vanadium Co., Rifle, Colo.
Climax Uranium Co., Grand Junction, Colo.
Vanadium Corporation of America, Durango, Colo.

[34] Stanford Research Institute, Industrial Uses of Radioactive Fission Products, A Report to the United States Atomic Energy Commission: Stanford, Calif., 1951, 102 pp.
[35] U. S. Atomic Energy Commission, Bonus for Initial Production of Uranium Ores from Domestic Mines. Effective March 1, 1951, through February 28, 1954: Domestic Uranium Program, Circ. 6, June 27, 1951, 2 pp.

Digitized by Google

Vanadium Corporation of America, Naturita, Colo.
Vanadium Corporation of America, Hite, Utah.
Vitro Chemical Co., 600 West 33d St. South, Salt Lake City, Utah.

Commission ore-buying stations (operated by the American Smelting & Refining Co., on behalf of the AEC) were located at Monticello and Marysvale, Utah.

Since April 1948, the AEC had offered a $10,000 bonus—through December 31, 1951, not collected—for discovery of a new deposit and production therefrom of the first 20 short tons of domestic uranium ore or mechanical concentrate assaying 20 percent or more uranium oxide. The new bonus was in addition to and did not supersede this old one. According to the AEC, the new bonus differed from the old one as follows:

1. Whereas the old bonus applied only to ores or mechanical concentrates assaying 20 percent or more uranium oxide (very high grade), the new bonus provided for payments for ores containing as low as 0.10 percent uranium oxide, and for maximum payments for ores assaying as low as 0.20 percent.
2. Whereas the old bonus was paid only after 20 short tons of ore was delivered to a qualified mill or ore-buying station, the new bonus would be paid on each pound of uranium oxide sold in acceptable ores up to and including the first 10,000 pounds.
3. Whereas the old bonus did not apply to carnotite-roscoelite ores of the Colorado Plateau, the new bonus would apply.

The new schedule of guaranteed minimum prices for carnotite-roscoelite ores of the Colorado Plateau,[36] effective March 1, 1951, through March 31, 1958, increased the base price paid for uranium ores containing as little as 0.10 percent uranium oxide from 50 cents per pound to $1.50 per pound, and for ores containing 0.20 percent uranium oxide or more from $2 per pound to $3.50. In addition, the premium paid on ores containing more than 4 pounds of uranium oxide to the ton was increased from 25 cents to 75 cents per pound (*see* Minerals Yearbook, 1949, p. 1254). The new price schedule follows:

U_3O_8 percent:	*Price per pound U_3O_8*	U_3O_8 percent:	*Price per pound U_3O_8*
Less than 0.10	No payment	0.15	$2.50
0.10	$1.50	.16	2.70
.11	1.70	.17	2.90
.12	1.90	.18	3.10
.13	2.10	.19	3.30
.14	2.30	.20 and more	3.50

The new schedule provided for the same development and haulage allowances that were in effect previously, also for the same payment for contained V_2O_5, the same additional premium for U_3O_8 in excess of 10 pounds U_3O_8 per short ton, and for the same limits on contained lime ($CaCO_3$). High-lime carnotite-roscoelite ore continued salable throughout 1951 at the Monticello, Utah, plant of AEC under special contracts, and the previously guaranteed minimum price for ores other than the carnotite-roscoelite type was unchanged in 1951. (*See* Minerals Yearbook, 1949, pp. 1254–1255.)

On March 29, 1951, the AEC announced that it would accept at its Monticello and Marysvale, Utah, ore-purchase depots copper-bearing uranium ores that met the specifications of Domestic Uranium Pro-

[36] U. S. Atomic Energy Commission, Guaranteed Minimum Price for Uranium-Bearing Carnotite-Type or Roscoelite-Type Ores of the Colorado Plateau. Effective March 1, 1951, through March 31, 1958: Domestic Uranium Program, Circ. 5, Revised Feb. 26, 1951, 2 pp.

Digitized by Google

gram Circular 5, revised,[37] with reference to U_3O_8 content, lime content, physical characteristics, and impurities. Purchases were made under contractual arrangements with individual producers.

Prices established in 1950 for low-grade development ore from Marysvale, Utah, area continued in effect throughout 1951. (*See* Minerals Yearbook, 1950, p. 1265.)

TABLE 3.—Consumption of uranium and thorium compounds for nonenergy purposes in the United States, 1947–51, in pounds of contained U_3O_8 and ThO_2

[U. S. Atomic Energy Commission]

Industry	1947	1948	1949	1950	1951
URANIUM (U_3O_8 EQUIVALENT)					
Chemical (including catalytic)	2,400	1,993	2,426	2,835	2,016
Ceramic (including glass)	825	385	270	938	875
Photographic		225			
Electrical	150	200	103	33	88
Total U_3O_8	3,375	2,803	2,799	3,806	2,979
THORIUM (ThO_2 EQUIVALENT)					
Gas-mantle manufacture	26,658	36,697	44,621	48,471	31,132
Refractories and polishing compounds	3,110	1,634	1,847	1,889	3,382
Chemical and medical	1,176	1,767	596	2,097	6,246
Electrical	1,283	427	237	314	1,457
Total ThO_2	32,227	40,525	47,301	52,771	42,217

Uranium.—High-purity uranium metal was available throughout 1951 to AEC licensees at about $50 a pound. The metal, in the form of pencil-size rods about 4 inches long, was produced by Mallinckrodt Chemical Co., St. Louis, Mo., and distributed to all the major chemical companies, from which the metal was available to the licensees in its original rod form, as rolled sheets, and as foil.

Radium.—Radium was quoted throughout 1951 at $20 to $25 per milligram; one source, however, offered radium element throughout the year at $16.00 to $21.50 per milligram, depending on quantity.

Isotopes.—Isotopes were available in 1951 through the Isotopes Division of the AEC in a somewhat wider range than in 1950, with prices generally unchanged. Isotopes available included those produced at the Oak Ridge National Laboratory, Argonne National Laboratory, and Brookhaven National Laboratory, of the AEC; at Chalk River, Ontario, Canada; and at Amersham and Harwell, England.[38] All isotopes used to study, diagnose, or treat cancer and allied diseases were made available by the Isotopes Division free of production costs. In September 1951 the AEC made arrangements with Stanford Research Institute of Stanford, Calif., to study the cost and pricing structure of the isotope distribution program.[39]

Thorium.—Thorium metal was quoted in 1951 by 1 producer, f. o. b. producer's plant, per gram in lots of less than 200 grams per item, in the form of powder, 45 cents, unsintered bars, 50 cents, sintered bars, 65 cents, sheet—0.005 inch and over, 75 cents, and sheet—0.002 to

[37] Work cited in footnote 36.

Digitized by Google

0.0049 inch, 85 cents; and in lots of 200 grams or more per item, at 35, 40, 50, 60, and 70 cents per gram, respectively.

Average prices in 1951 for thorium nitrate and oxide were reported by a large producer in 100-pound lots, f. o. b. producer's plant, as follows: Thorium nitrate, mantle grade—domestic price $2.20, export $3.35 per pound; thorium oxide, 97 percent ThO_2—domestic price $5.40 per pound; thorium oxide, photographic-lens grade, 99 percent ThO_2—domestic price $11.45 per pound.

FOREIGN TRADE [40]

Deliveries of uranium concentrates to the AEC from the Belgian Congo and Canada continued at scheduled rates during 1951. Cumulative exports of radioisotopes reported by the AEC as of November 30, 1951, reached 1,213 shipments distributed among 33 different nations.[41] Data are not disclosed on imports and exports of uranium and thorium ores, concentrates, metal, alloys, and compounds.

In July 1951 the AEC enlarged its radioisotope export program to include all radioactive materials sold in the United States except hydrogen-3 (tritium) and for the first time made radioisotopes produced in the United States available to foreign users for industrial research and applications. The action increased the number of different radioactive isotopes available for export from 26 to 99.[42]

TABLE 4.—Radium salts imported for consumption in the United States, 1947–51

[U. S. Department of Commerce]

Year	Radium salts			Radioactive substitutes (value)
	Milligrams	Value		
		Total	Average per gram	
1947	76,681	$1,504,814	$19,600	----------
1948	77,018	1,385,337	17,900	$6,273
1949	98,032	1,719,656	17,500	370
1950	80,969	1,235,511	15,300	6,106
1951	89,805	1,225,564	13,600	5,399

WORLD REVIEW

In the deliberations by the United Nations on disarmament during 1951, proposals of the United States were adopted by the Committee of Twelve, consisting of representatives of the 11 Security Council members and Canada (*see* Uranium, Radium, and Thorium chapter, Minerals Yearbook, 1950), as the basis of a report to the next Assembly. The Sixth General Assembly opened in Paris on November 6, 1951, with a 10-day general debate on the state of the world. A tripartite proposal by France, the United Kingdom, and the United States was

[40] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.
[41] Work cited in footnote 2, p. 151.
[42] U. S. Atomic Energy Commission, Washington, D. C., Press Release: July 15, 1951, 4 pp.

Digitized by Google

adopted on December 19 by the First Committee and presented to the General Assembly in the form of a resolution which, at the year end, was still under consideration; the resolution read, in part, as follows: [43]

> The General Assembly * * * directs the Disarmament Commission to prepare proposals to be embodied in a draft treaty (or treaties) for the regulation, limitation, and balanced reduction of all armed forces and all armaments, for the elimination of all major weapons adaptable to mass destruction, and for effective international control of atomic energy, the prohibition of atomic weapons and the use of atomic energy for peaceful purposes only.

Under an amendment to the Atomic Energy Act, approved by President Truman on October 30, 1951, wider exchange of nonweapon data was permitted with nations that do not threaten the security of the United States; the amendment read, in part, as follows: [44]

> Section 10 (a) is hereby amended by inserting the following subsection 10 (a) (3) after subsection 10 (a) (2):
> "(3) Nothing contained in this section shall prohibit the Commission, when in its unanimous judgment the common defense and security would be substantially promoted and would not be endangered, subject to the limitations hereinafter set out, from entering into specific arrangements involving the communication to another nation of restricted data on refining, purification, and subsequent treatment of source materials; reactor development; production of fissionable materials; and research and development relating to the foregoing * * * ."

The third American-British-Canadian conference on radiation-detection instruments was held at the Atomic Energy Research Establishment, Harwell, England, beginning April 30, 1951. The conference lasted 2 weeks, with the first week devoted to technical discussions on the design and application of radiation-detection instruments and the second week to visits to the facilities of British instrument manufacturers.[45]

WESTERN HEMISPHERE

Canada.—On January 2, 1951, approval by the Canadian Government was announced for construction of another reactor at Chalk River, Ontario, Canada's nuclear energy research center. Experience gained in operation of the two other reactors at Chalk River was to be used in designing the new reactor, which was to cost about C$30 million and employ heavy water as a moderator.[46]

Virtually all the uranium ore produced in Canada in 1951 came from the mine of the Crown company, Eldorado Mining & Refining (1944), Ltd., at Port Radium, on Great Bear Lake, N. W. T. Owing to a fire on November 9 which destroyed the crushing plant and mill at the property, ore production for the year was 13 percent less than in 1950. Development footage and exploratory diamond drilling totaled 13,101 feet and 54,715 feet, respectively, compared with 13,388 and 26,148 feet in 1950. Year-end estimates indicated that ore reserves were being maintained.[47]

Outstanding in the search during 1951 for new sources of uranium in Canada was the increased activity that prevailed in the Goldfields

Digitized by Google

district of Saskatchewan, on the north shore of Lake Athabaska. Eldorado Mining & Refining (1944), Ltd., the principal company operating in the area, advanced substantially development of its properties along the north shore of Beaverlodge Lake. Development on its Ace and Eagle claims included deepening of the Ace shaft from 599 to 1,143 feet, 7,150 feet of drifting and cross-cutting, and 34,803 feet of exploratory diamond drilling. The underground program on the Eagle property was discontinued in June and equipment moved to the Fay zone, about 4,000 feet southwest of the Ace shaft, where sinking of a 5-compartment production shaft had reached a depth of 72 feet at the year end. A large surface construction program was to be undertaken in 1952, including erection of a concentrator; production operations were scheduled to begin early in 1953.[48] Extensive exploration and development operations by private interests in 1951 were also underway in the Goldfields district and in the Black Lake-Charlebois Lake region, about 140 miles east of Goldfields. In Ontario activity centered mainly in the Sault Ste. Marie and Wilberforce regions and in British Columbia in the Hazelton district and at Birch Island, about 80 miles north of Kamloops. Exploration continued in the Great Bear Lake, Hottah Lake, and Marian River regions of Northwest Territories.[49] Geologic and economic features of Canadian uranium deposits were discussed in the technical press.[50]

On March 6, 1951, announcement was made that producers of Canadian uranium would receive henceforth a development allowance of C$1.25 per pound of contained U_3O_8 during the first three years of production. At the same time the period of a guaranteed market price was extended by 2 years from April 1, 1958, to April 1, 1960. The announcement, in effect, raised Canadian prices for uranium to a level comparable with that established on March 1, 1951, in the United States by the AEC.[51]

A commercial beam therapy unit employing cobalt-60 produced at Chalk River, Ontario, was installed in the Victoria Hospital, at London, Ontario. The unit was the first of its kind produced in the world. Selling price of the unit was C$48,000; a therapy unit employing radium with an equivalent dosage would cost approximately C$45,000,000.[52]

Chile.—The Chilean Government announced in 1951 that pitchblende had been found in the tailings at old copper mines near Carrizal, north of Vallenar, in Atacama Province, and near Tambillos, south of La Serena, in Coquimbo Province.[53]

Mexico.—Discoveries of uranium deposits in Mexico were reported during 1951 at El Guichi, near Eldorado, Culiacán district, Sinaloa;[54]

near Susucato, Zitacuaro district, Michoacan; and in the mountains near the city of Oaxaca, Oaxaca.[55]

EUROPE

Germany.—Significant deposits of uranium ore were found in North Bavaria during 1951, according to reports. The deposits are situated in a zone about 100 kilometers long that extends southeast from Amberg toward the Czechoslovak border.[56] Uranium deposits were discovered in old mine workings near Wittichen, in the Klosterbach Valley, where silver- and cobalt-bearing ore was formerly mined.[57]

Italy.—Exploration was begun in 1951 under Government auspices of the uranium occurrences found in the Province of Trento, in the Fersina River Valley. Autunite and torbernite occurrences were discovered in the Province of Cuneo near Lurisia and in the Pesio Valley.[58] Italo-French interests applied to the Italian Government for a concession for exploiting uranium occurrences found in the St. Vincent area of the Aosta Valley.[59] The Sardinian Regional Government announced plans to take over development of the uranium deposits discovered in the Decimomannu region.[60]

Norway.—After 3 years of planning and building, the Norway-Netherlands reactor at Kjeller, near Oslo, Norway, went into operation on July 30, 1951, and the following afternoon the reactor produced its first radioactive isotope.[61] Heavy water is used as the moderator in the reactor, which has a rating of 100 kilowatts. Norway provided the heavy water, and the Netherlands furnished the uranium. The reactor will be utilized for the production of isotopes, neutron research, research on metals and materials, and the peaceful applications of atomic energy.[62] An article describing the constructional details of the reactor was published.[63]

Sweden.—A large deposit containing uranium was discovered at Guliksberg, near Anund Lake, in Swedish Lapland. Preliminary surveys indicated an ore body 1,900 feet long and 1,000 feet wide.[64] Proposed construction of a reactor near the research station of the Academy of Sciences in Stockholm, was announced.[65]

U. S. S. R.—The second and third atomic explosions by the Soviet Union were announced by the White House on October 3 and October 22, 1951, respectively; detection of the first atomic explosion had been revealed by President Truman on September 23, 1949.[66] Torbernite deposits were reported to have been discovered in 1951 near Lake Ochrida, in Albania, by members of a Russian Mission. The uranium ore was to be exploited under supervision of engineers from the Russian Mining Office, at Budapest, Hungary.[67] Important resources of uranium ore were said to have been found in the Rhodope mountains

of Bulgaria, and the formation of a State-controlled mining company to exploit the deposits was announced by the Bulgarian Government.[68] A new uranium mine was reportedly opened in 1951 at Hermanovw Seisy, near Jachymov, in Czechoslovakia,[69] [and [uranium ore discovered near Pribram on the site of an old silver mine.[70] Late in 1951 Lt. Col. Fedya Astrachov, head of Russia's uranium-mining project in East Germany, and a Stalin prize winner, fled to freedom in the West.[71]

United Kingdom.—During 1951 two reactors, both producing plutonium, were placed in operation at Sellafield, Cumberland, England.[72] Drawings and estimates of a prototype atomic power unit for large merchant ships and warships were reportedly being prepared by an engineering firm under contract to the British Government.[73] In November 1951 the Ministry of Supply offered increased prices for uranium ores and concentrates to prospectors in the Colonies and Dependent Territories, bringing the prices in line with those offered by the United States and Canada. The Ministry also announced that it was willing to discuss purchase terms for thorium-bearing minerals.[74]

AFRICA

Morocco.—Moroccan government sources reported in 1951 the discovery of uranium minerals at Bouazzer and Azegour in the South Atlas Mountains. The occurrence at Bouazzer was said to be complex and difficult to exploit, whereas that at Azegour was described as a pitchblende occurrence.[75]

Mozambique.—Under an agreement reportedly concluded between the French Government and a Portugese mining group, over 100 tons of uranium ore was shipped about the beginning of 1951 to France from the Tete district.[76]

Union of South Africa.—In 1951 2 more gold-mining companies operating on the Witwatersrand joined the list of prospective producers of uranium, bringing the total of such companies to 6 (*see* Uranium, Radium, and Thorium chapter, Minerals Yearbook, 1950). The 2 additional companies were the Stilfontein Gold Mining Co., Ltd., and West Driefontein Gold Mining Co., Ltd.; production of uranium by the 2 companies was expected to begin in 1953.[77] The AEC announced that the construction of plants in South Africa to recover uranium from gold-ore residues was proceeding on schedule;[78] initial production of uranium was expected in the second half of 1952 by West Rand Consolidated Mines, Ltd.[79] In a discussion of the gold-uraninite mineralization of the Witwatersrand deposits evidence

was presented in a paper published in 1951 that tended to support the hypothesis that the deposits are of hydrothermal origin.[80]

ASIA AND AUSTRALIA

Australia.—The uranium occurrence at Rum Jungle, near Darwin, Northern Territory, and that at Radium Hill, near Olary, South Australia, were the scenes of much activity in 1951. Mining of ore was begun at Rum Jungle; two shafts were sunk, and a water supply was brought to the field. The discoverer of the deposit was paid a reward of $2,240 on the basis that 25 tons of uranium oxide would be produced. Further payment of $4,480 will be made for each additional 25 tons until total payments reach $56,250, the maximum payment for any uranium discovery in Australia.[81]

Under an arrangement with the Commonwealth Government, the Government of South Australia agreed to undertake the mining of uranium at Radium Hill. Exploratory work was performed by the South Australian Mines Department concurrently with investigation of the Mount Painter area in the Flinders Ranges. Geophysical surveys were reported to have been favorable for an extensive occurrence. A large area was, in consequence, reserved from operations under the Mining Act, indicating that the area would be investigated solely by the Mines Department.[82]

The first discovery of uranium in Victoria was made at Sunnyside, a gold-mining center in the mountains of East Gippsland. Active exploration of the area was planned.[83] An area of about 100 square miles surrounding the uranium occurrence along the banks of the Ferguson River near Katherine, 200 miles south of Darwin, was declared a Crown reserve by the Northern Territory Mines Branch. Geophysicists of the Commonwealth Bureau of Mineral Resources were planning to examine the area.[84]

China.—According to a press report originating in New Delhi, India, said to be based on statements by refugees from Sinkiang Province in northwest China, Russia has constructed an atomic plant in the Ili district, near the Soviet border. Prof. Bruno Pontecorvo, a nuclear scientist who defected to the U. S. S. R. in 1950 (*see* Uranium, Radium and Thorium chapter, Minerals Yearbook, 1950), was alleged to be working at the plant.[85] Other press reports from Taipei, Formosa, were to the effect that arrangements had been made to mine uranium ore near Ining, in the vicinity of the Ili district, and that a range for testing atomic bombs had been established along the northern fringe of the Takla Makan, a desert 275 miles southwest of Tihwa, the capital of Sinkiang.[86]

India.—Discovery of two uranium-bearing belts in Eastern and Central India was announced by the Minister of Natural Resources

and Scientific Research.[87] The Directorate of Mines, Rajasthan Government, stated that uranium had been found in the Aravalli Hills, about 20 miles from Udaipur.[88] India's first nuclear reactor, to be used for research purposes and the production of radioisotopes, was to be built within 2 years, with France cooperating in its construction.[89] A search for uranium deposits in the Gilgit region and the Hindukush Ranges in Baluchistan, Pakistan, was reported.[90]

Vanadium

By Hubert W. Davis

GENERAL SUMMARY

THE CENTER of vanadium-ore mining in the United States is the Colorado-Utah region, where it is produced chiefly as a byproduct of uranium. For security reasons, publication of figures on production and consumption of vanadium ore in the United States has been suspended since 1947 at the request of the Atomic Energy Commission. Small outputs are made in Arizona, Nevada, and New Mexico. Some vanadium is recovered as a byproduct of phosphate rock mined in Idaho. Vanadium is also recovered as a byproduct of chrome ore at Glens Falls, N. Y., and as a byproduct of petroleum residues at Wood-Ridge, N. J.

Imports of vanadium concentrates in 1951 were 33 percent less than in 1950, but receipts of ferrovanadium declined only 5 percent. Exports of ferrovanadium in 1951 were 48 percent more than in 1950.

On March 8, 1951, the quotation on vanadium ore was advanced to 31 cents a pound of contained vanadium; the former price was 27½ cents.

TABLE 1.—Vanadium in ores and concentrates produced in the United States, 1938–47 [1]

Year	Pounds	Year	Pounds
1938	1,613,155	1943	5,586,492
1939	1,984,068	1944	3,527,054

USES

About 90 percent of the vanadium used is consumed as ferrovanadium in the manufacture of tool steels, engineering steels, high-strength structural steels, nonaging rimming steels, and special wear-resistant cast irons. Some ferrovanadium is used in welding-electrode

Digitized by Google

coatings and as a deoxidizer, and some metal is utilized in magnets. Some vanadium oxide is also used in the production of tool steel. The largest uses of vanadium oxide and ammonium metavanadate are as catalysts, in glass and ceramic glazes, for driers in paints and inks, and for laboratory research. Ductile vanadium, 99.8 to 99.9 percent pure, was made available in 1950.[1]

According to Steel:[2]

Vanadium is one of the most recent of the rare metals to become industrially available. Pure vanadium metal has been rare, even though alloys of vanadium have been produced in quantity for many years. It has been considered a rare metal primarily because it is difficult to produce in the metallic state without the addition of alloying elements.

Vanadium is eighth in order of natural abundance of those metals useful for structural purposes. In this respect it ranks ahead of nickel and copper.

Pure, ductile vanadium metal can now be obtained in massive form for remelting, as well as in ingots, bars, sheet, and foil. The metal is lighter than iron, has good structural properties, and resists pitting and corrosion by salt spray and sea water. It can be rolled at ordinary temperatures; cold reductions up to 85 percent have been made without annealing. Pure vanadium machines well and is easily welded with regular shielded arc methods.

PRICES

For many years vanadium ore has been quoted at 27½ cents a pound of contained V_2O_5, but on March 8, 1951, it was advanced to 31 cents. This quotation, however, disregards the grade of the ore or the presence or absence of objectionable impurities—matters important to the refiners, inasmuch as impurities vitally affect recovery. Throughout 1951 vanadium pentoxide (technical grade) was quoted at $1.06 to $1.28 a pound of V_2O_5 and ferrovanadium at $3 to $3.20 a pound of contained vanadium (depending upon grade of the alloy).

FOREIGN TRADE[3]

Imports of vanadium concentrates (all from Peru) were 982,878 pounds (contained vanadium) in 1951, a decrease of 33 percent from 1950. There were no imports of vanadium-bearing flue dust in 1951. Imports of ferrovanadium were 123,050 pounds (gross weight) valued at $100,261 in 1951 compared with 130,022 pounds valued at $91,193 in 1950. The 1951 imports comprised 70,810 pounds from Japan, 19,800 pounds from France, 18,910 pounds from United Kingdom, and 13,530 pounds from Germany. Vanadium ore and concentrates enter the United States free of duty. However, the rate of duty on ferrovanadium is 12½ percent ad valorem and on vanadic oxide, anhydride, salts, and compounds and mixtures of vanadium, 40 percent ad valorem.

TABLE 2.—Vanadium ore or concentrates and vanadium-bearing flue dust imported for consumption in the United States, 1942–51

[U. S. Department of Commerce]

Year	Vanadium ore or concentrates			Vanadium-bearing flue dust		
	Pounds		Value	Pounds		Value
	Gross weight	Vanadium content		Gross weight	Vanadium content	
1942	36,492,268	2,422,376	$1,274,483	624,423	154,028	$29,545
1943	22,117,131	2,052,620	1,080,150	748,749	64,393	53,553
1944	4,247,490	1,284,603	633,719	191,901	40,171	28,059
1945	8,776,328	1,550,479	725,362	133,795	26,293	19,378
1946	2,784,349	791,057	390,077	97,750	20,931	13,480
1947	3,274,548	983,869	448,076	143,124	71,819	15,483
1948	4,034,509	1,051,675	534,374			
1949	2,028,980	551,337	272,124			
1950	5,110,403	1,457,010	708,806	9,575	804	2,475
1951	3,893,900	982,878	526,941			

Exports of vanadium ore and concentrates totaled 2,817 pounds (contained vanadium) valued at $6,581 in 1951 compared with 963 pounds valued at $2,615 in 1950. The 1951 exports comprised 2,386 pounds to Canada and 431 pounds to France. Exports of ferrovanadium totaled 122,344 pounds (gross weight) valued at $190,346 in 1951 compared with 82,449 pounds valued at $183,307 in 1950. The 1951 exports comprised 118,931 pounds to Canada and 3,413 pounds to Austria. Exports of vanadium metal, alloys, and scrap were 1,712 pounds valued at $6,481 in 1951 compared with 4,106 pounds valued at $2,688 in 1950. The 1951 exports comprised 1,710 pounds to Canada and 2 pounds to United Kingdom.

WORLD REVIEW

World production of vanadium ores is limited almost entirely to four countries—Northern Rhodesia, Peru, South-West Africa, and the United States. From 1941 through 1947 output from these sources ranged from 1,400 to 4,400 metric tons, with the United States the leading producer.

Vanadium has also been recovered commercially from phosphate rock, iron ore, chrome ore, magnetite beach sands, caustic soda solution employed in the Bayer process of refining bauxite, naphtha soot collected from the smokestacks of ships and industrial plants, and vanadiferous ashes derived from asphaltites.

Because complete information on the quantity of vanadium recovered as byproducts of iron ore and other raw materials is lacking, it is not possible to determine world production of vanadium from all sources. Consequently, table 3 reflects only the production of vanadium in ores and concentrates for the countries listed, plus the quantity recovered in the United States as a byproduct of phosphate rock.

Argentina.—Vanadium occurs in small deposits widely scattered in the Provinces of Córdoba and San Luis. A small quantity of ore is mined for the production of 3 to 6 metric tons of vanadium pentoxide annually.

Total [5]	3,865	4,384	2,757	2,674	1,403	1,741	(4)	(4)	(4)	(4)

[1] Figure not available.
[2] Estimate.
[3] Includes vanadium recovered as a byproduct of phosphate-rock mining.
[4] United States figures for 1948–51 withheld at request of Atomic Energy Commission.
[5] Total represents data only for countries shown in table and excludes vanadium in ores produced in French Morocco, Spain, and U. S. S. R., for which figures are not available; the total also excludes quantities of vanadium recovered as byproducts from other ores and raw materials.

Northern Rhodesia.—The Rhodesia Broken Hill Development Co., Ltd., is the only producer of vanadium in Northern Rhodesia. Output of vanadium oxide was 167 long tons averaging 91.32 percent V_2O_5 in 1951. There was no production in 1950, although shipments were made from stock. Feed to the vanadium leach plant in 1951 was derived from various sources and totaled 10,120 short tons averaging 2.82 percent V_2O_5. Recovery of vanadium was 60.3 percent, which was considered satisfactory in view of the low grade of the material treated. According to the company:

> It is becoming increasingly difficult to maintain a continuous supply of vanadium bearing material with a grade suitable for leaching, because of the gradual exhaustion of accumulated surface dumps. Much experimental work has been carried out in an effort to produce a leach grade concentrate from the low grade mixed fines tailings and recent flotation tests have been encouraging.

Peru.—The famous Mina Ragra mine of the Vanadium Corp. of America in the Andes near Ricran, Department of Junin, has been an important source of vanadium since 1907, when production was begun. Output in Peru was about 700 metric tons of V_2O_5 in 1951 compared with 779 tons of V_2O_5 in 1950.

South-West Africa.—The Abenab West lead-vanadium mine of the South West Africa Co., Ltd., was the only producer of vanadium in South-West Africa in 1951. Output of concentrates (V_2O_5 content) was about 600 short tons in 1951 compared with 580 tons in 1950. Exports of concentrates were 3,151 short tons averaging about 12.6 percent V_2O_5 in 1951, all of which went to Europe.

Zinc [1]

By O. M. Bishop and Esther B. Miller

GENERAL SUMMARY

THE DEMAND engendered by the National Defense Program prompted the domestic zinc industry to smelt the greatest quantity of slab zinc and mine the largest tonnage of recoverable zinc since the war year 1943. Smelter output, 2 percent above the 1950 level, totaled 930,000 short tons (67 percent from domestic ores, 28 percent from foreign ores, and 5 percent from secondary material). Domestic mine production of recoverable zinc was 681,000 tons or 9 percent above the 623,000 tons of 1950. Montana, with 86,000 tons, led all the States in mine production of zinc, followed in order by Idaho, New Jersey, Colorado, Oklahoma, Arizona, amd New Mexico. Imports of zinc in ores and concentrates increased 9 percent to 303,000

Digitized by Google

short tons, but imports of slab zinc declined 44 percent to 88,000 short tons. Consumption of slab zinc, curtailed by the restrictive orders of the National Production Authority, declined 3 percent to 934,000 tons in 1951, a consumption exceeded only by the alltime peak year 1950. Although inventories of slab zinc at producers' plants increased by 13,000 tons, they remained at a relatively low level. Consumers' stocks declined by 14,000 tons to 50,000 short tons, the equivalent of requirements for 19 days. Zinc prices were controlled by the Office of Price Stabilization throughout 1951. The price for Prime Western grade at East St. Louis was 17.50 cents per pound for most sellers until October 2, 1951, when an increase of 2 cents per pound was authorized and made.

GOVERNMENT REGULATIONS

In 1950 the Korean War caused a prompt acceleration of the Nation's defense program, which necessitated introducing Government controls in the latter part of the year. Regulatory measures instituted in 1950 are described in the Zinc chapter of Minerals Yearbook, 1950.

Among the 1950 measures was National Production Authority Order M–15, effective December 1, 1950, which limited civilian consumers of zinc and zinc-metal products to an average quarterly consumption rate not to exceed 80 percent of their quarterly average as established in the 6-month period ended June 30, 1950. The same order specified that inventories should not exceed a 45-day supply or a "practicable minimum working inventory," whichever was less. On June 15, 1951, Order M–15 was amended to limit quarterly consumption of Special High-Grade zinc to 70 percent of that used in the base period, and allowable inventories of zinc and zinc metal products were restricted to 30 days or the "practicable minimum working inventory," whichever was less. On July 5 NPA issued a new Order M–9, which placed slab zinc under allocation effective August 1. Under this order no dealer or consumer could accept delivery of 20 short tons or more of slab zinc during any calendar month without an allocation authorization.

DOMESTIC PRODUCTION

Statistics on zinc production are compiled both on a mine and on a smelter basis. The mine-output data, based upon the zinc content of ores and concentrates produced (adjusted to account for average smelting losses), form an accurate measure of domestic zinc output from year to year. Smelter production of slab zinc from domestic ores represents a more accurate figure of actual zinc recovery but usually differs from the mine figure owing to a time lag between mine or mill shipments and smelter production. Over a period of years, these variations tend to balance within the limits of statistical error.

MINE PRODUCTION

Zinc mining in the United States is centered largely in six areas—the Tri-State area of southeastern Kansas, southwestern Missouri, and northeastern Oklahoma; Tennessee-Virginia; Sussex County,

Digitized by Google

N. J.; St. Lawrence County, N. Y.; northern Illinois-Wisconsin; and the Western States (principally Montana, Idaho, Colorado, Arizona, New Mexico, Utah, Washington, Nevada, and California, in descending order of production in 1951).

Grand total	684,011	637,608	629,977	593,203	623,375	681,189

Mine production of recoverable zinc (including that recovered as zinc pigments and salts directly from ore) increased to 681,000 tons in 1951 or 9 percent above the 1950 total. This high output was achieved despite a 2-week shutdown of mines, mills, and smelters caused by a strike in the Western States in late August and early September. The combined Western States provided 58 percent (59 percent in 1950) of

TABLE 3.—Mine production of recoverable zinc in the United States,[1] 1950–51, by months, in short tons

the total output, the States east of the Mississippi River 28 percent (28), and the West Central States—Arkansas, Kansas, Oklahoma, and Missouri—14 percent (13).

Montana was the leading zinc-producing State, the output being the greatest since 1920. The production was chiefly from the Butte Hill area, the East Helena slag dump, and the Mike Horse and Jack Waite properties.

Idaho, which has held first place in tons of zinc mined since 1943, yielded that position to Montana in 1951. About 96 percent of the State total came from the Coeur d'Alene region and most of the remainder from the Warm Springs district.

Colorado exceeded its 1950 production by 22 percent. Mines in Eagle County produced 52 percent of the State zinc in 1951, San Miguel 17 percent, Lake 15 percent, and other counties 15 percent.

Arizona zinc output declined 12 percent in 1951 owing to a decrease in output of zinc-lead ores from the Copper Queen mine at Bisbee.

New Mexico output of zinc, the highest since 1944, was 55 percent above the 1950 production despite the strike throughout the year at the Hanover mine of New Jersey Zinc Co.

Zinc output in Utah in 1951 was 8 percent higher than in 1950. The United States and Lark property continued to be the largest producer.

Zinc production in Washington was at an alltime high in 1951. The Grandview, Pend Oreille, Deep Creek, and Holden mines supplied 98 percent of the State production.

Zinc output in Nevada declined 19 percent as production from the Pioche district dropped from 19,650 tons to 14,350. Oxidized ores from operating mines and the former Metals Reserve Company Clark County stockpile were shipped to the Tooele, Utah, slag-fuming plant.

California mine output of zinc increased 27 percent over 1950. The Darwin and Shoshone groups and the Afterthought and Penn mines supplied virtually the entire output. The Carbonate King mine produced some oxidized zinc ore, which was treated at a slag-fuming plant.

Zinc production in the Tri-State district increased 14 percent in 1951, largely in response to the substantial rise in lead and zinc concentrate prices.

Zinc production from mines in the States east of the Mississippi River in 1951 was 9 percent higher than in 1950. The principal produc-

[1] Includes very small quantity produced elsewhere in State.
[2] No production in Iowa since 1917.
[3] Includes Peshastin Creek and Wenatchee River districts.
[4] Quantity withheld to avoid disclosure of individual company operations.
[5] This district is not listed in order of 1951 output.

Digitized by Google

ing mines were the Franklin and Sterling Hill mines, New Jersey; the Balmat mine, New York; the Mascot No. 2 mine, Tennessee; the Edwards mine, New York; the Davis-Bible group, Tennessee; the Bautsch mine, Illinois; the Calumet mine, Wisconsin; the Austinville mine, Virginia; and the Grasselli mine, Tennessee. These nine mines or mine groups furnished 82 percent of the zinc mined east of the Mississippi River.

The 25 leading zinc-producing mines in the United States in 1951, listed in table 4, yielded 60 percent of the total domestic zinc output; the 3 leading mines produced 25 percent and the 6 leading mines 35 percent.

Detailed information on the production of mines and mining districts in the United States may be found in the chapters of this volume dealing with the mine production of gold, silver, copper, lead, and zinc in the various States.

SMELTER PRODUCTION

During 1951, 18 primary zinc-reduction plants were in operation; 9 operated with horizontal retorts exclusively, 4 with vertical retorts exclusively (1 electrothermic), and 5 with electrolytic methods.

Horizontal-Retort Plants.—The total number of retorts reported at horizontal-retort primary plants in 1951 was 54,624, the same as in 1950. Of the total retorts reported, 52,484 were in use at the close of 1951, again the same as in 1950.

Vertical-Retort Plants.—Four vertical-retort continuous distilling plants operated during 1951. The total number of vertical retorts increased from 88 on December 31, 1950, to 89 at the end of 1951. At the close of 1951, 84 vertical retorts were in operation.

Electrolytic Plants.—Five electrolytic zinc-reduction plants were in operation during 1951. There was a total of 3,370 cells at the plants on December 31, 1951, of which 3,340 (99 percent) were in operation. The number of cells at the end of 1950 was 3,360, of which 3,322 (99 percent) were operating.

Smelting Capacity.—Irrespective of additions or subtractions of smelter recovery units, statistics on domestic smelting capacity vary from year to year, owing to changes in metallurgical practices among the various plants. According to reports to the Bureau of Mines, the zinc-reduction plants in the United States on December 31, 1951, had a stated annual capacity of 1,082,610 tons of slab zinc under normal operating conditions, allowing for necessary shutdowns for repairs. This figure, which compares with a 1,044,000-ton reported capacity at the end of 1950, indicates that 1951 output was 86 percent of capacity. Horizontal- and vertical-retort plants operated at 86 percent of a stated 650,900-ton capacity (86 percent of a 619,000-ton capacity in 1950), electrolytic plants at 90 percent of a 375,000-ton capacity (93 percent of 369,000-ton capacity in 1950), and secondary smelters at 57 percent of a 56,710-ton capacity (69 percent of a 56,000-ton capacity in 1950).

Waelz Kilns and Slag-Fuming Plants.—During 1951 there was no change in the companies operating Waelz kilns or slag-fuming plants (see Minerals Yearbook, 1950, p. 1288, for a list of such companies).

The four slag-fuming plants in 1951 treated 606,116 tons of hot and

Digitized by Google

cold slag, which yielded 108,140 tons of oxide fume containing 74,672 tons of recoverable zinc. Corresponding figures for the four operating plants in 1950 were 652,172, 102,826, and 63,522 tons, respectively.

Expansion of slag-fuming facilities planned, as of the end of 1951, included capacity for 7,200 tons of recoverable zinc at the Herculaneum, Mo., smelter of the St. Joseph Lead Co., and 10,000 tons of recoverable zinc at the Selby, Calif., smelter of the American Smelting & Refining Co.

Active Zinc-Reduction Plants.—In July 1951 the New Jersey Zinc Co. began full-scale continuous operation of the first Sterling furnace [2] at its Palmerton, Pa., smelter. The patented process is a new method of smelting zinc ores using an electric arc to generate heat for the reduction. When an iron-bearing zinc ore, such as that from the Sterling Hill, N. J., mine is being smelted, 95 percent of the zinc is recovered in the condensers, and the iron is tapped from the furnace as pig iron. The process is equally well adapted to marmatitic zinc ores when roasted. Overall power consumption approximates 3,000 kw.-hr. per short ton of slab zinc produced.

In West Virginia the Matthiessen & Hegler Zinc Co. took over operation of the plant at Meadowbrook formerly operated by E. I. Du Pont de Nemours & Co. Otherwise, there was no change during the year with respect to zinc-reduction plants operating in the United States. (*See* Minerals Yearbook, 1950, pp. 1289 and 1290, for a list of such plants.)

SLAB ZINC

The output of primary slab zinc in 1951 was 5 percent above 1950 production and the highest since 1943. Output from domestic concentrates increased 6 percent and that from foreign concentrates 2 percent.

Production of redistilled slab zinc decreased 27 percent from the record output established in 1950. Of the 48,657 tons of redistilled secondary slab zinc produced in 1951, 16,251 tons (33 percent) was produced at primary smelters and 32,406 tons (67 percent) at secondary plants.

The output of remelted secondary slab zinc is not included with that of redistilled metal. In 1951 the quantity of slab zinc recovered by remelting purchased scrap was 4,454 tons (7,243 tons in 1950). Zinc rolling mills and other substantial consumers of slab zinc recover large quantities of zinc from scrap generated in their own plants, but metal so recovered is excluded from Bureau of Mines canvasses.

In addition to redistilled and remelted unalloyed secondary zinc, a large quantity of secondary zinc is recovered each year in the form of alloys, zinc dust, zinc pigments, and zinc salts. Additional information on secondary zinc is given in the Secondary Metals—Nonferrous chapter of this volume.

Strikes caused some production losses but did not impair output as seriously as in some years. The strike of mine, mill, and smelter workers in the Western States from August 23 to September 6 curtailed output in that area. Several other strikes of short duration at zinc-reduction plants curtailed production of slab zinc slightly.

TABLE 6.—Primary and redistilled secondary slab zinc produced in the United States, 1942–46 (average) and 1947–51, in short tons

Year	Primary			Redistilled secondary	Total (excludes zinc recovered by remelting)
	From domestic ores	From foreign ores	Total		
1942–46 (average)	544,990	[1] 294,271	839,261	48,841	888,102
1947	510,058	292,437	802,495	59,542	862,037
1948	537,966	249,798	787,764	62,320	850,084
1949	591,454	223,328	814,782	55,041	869,823
1950	588,291	[1] 255,176	843,467	66,970	910,437
1951	621,826	259,807	881,633	48,657	930,290

[1] Includes a small tonnage of foreign slab zinc further refined into high-grade metal in the United States.

Of the 1951 output of primary zinc, 62 percent was distilled and 38 percent produced electrolytically.

Production of Special High Grade, Brass Special, and Prime Western slab zinc increased 4, 29, and 1 percent, respectively, in 1951. Production of the Selected grade was over three times that of 1950. Output of Regular High Grade and Intermediate declined 9 and 4 percent, respectively. Of the total 1951 output (comparable 1950 figures in parentheses) 41 percent (41) was Prime Western, 30 percent (30) Special High Grade, 19 percent (21) Regular High Grade, 7 percent (5) Brass Special, 2 percent (2) Intermediate, and 1 percent (less than 1) Selected.

TABLE 7.—Distilled and electrolytic zinc, primary and secondary, produced in the United States, 1942–46 (average) and 1947–51, in short tons

CLASSIFIED ACCORDING TO METHOD OF REDUCTION

Year	Electrolytic primary	Distilled	Redistilled secondary [1]		Total
			At primary smelters	At secondary smelters	
1942–46 (average)	290,299	548,962	21,930	26,911	888,102

Montana continued to be the largest producer of primary slab zinc in 1951; Pennsylvania and Oklahoma were in second and third places, respectively. Of the States for which production statistics may be shown separately, Illinois, Idaho, and Arkansas occupied the next three positions. As usual, in Montana and Idaho slab zinc was produced by electrolytic methods only. In Illinois and Texas both electrolytic and distilled zinc metal were recovered, whereas in all other States zinc was produced by distillation exclusively.

TABLE 8.—Primary slab zinc produced in the United States, by States where smelted, 1942–46 (average) and 1947–51, in short tons

Year	Arkansas	Idaho	Illinois	Montana	Oklahoma	Pennsylvania	Texas and West Virginia [1]	Total	
								Short tons	Value
1942–46 (average)	31,363	37,110	156,280	204,275	98,414	207,051	104,768	839,261	$144,183,426
1947	17,158	41,801	113,192	197,453	128,398	193,524	110,969	802,495	171,894,429

[1] Includes Missouri, 1943–44 and 1947–51.

BYPRODUCT SULFURIC ACID

Sulfuric acid made from sulfur dioxide gases produced in roasting zinc blende (sphalerite) is an important byproduct of zinc smelting. To utilize a larger proportion of their acid-producing capacity, some plants also consume large quantities of native sulfur. Combined production of sulfuric acid from both these sources (*see* table 9) increased 5 percent in 1951.

TABLE 9.—Sulfuric acid (basis, 100 percent) made at zinc-blende roasting plants in the United States, 1947–51

Year	Made from zinc-blende [1]		Made from native sulfur		Total [1]		
	Short tons	Value [2]	Short tons	Value [2]	Short tons	Value [2]	
						Total	Average per ton
1947	598,703	$8,001,205	266,104	$3,556,281	864,807	$11,557,486	$10.38

1951	635,948	10,218,400	261,106	4,195,451	897,054	14,413,851	12.48

[1] Includes acid from foreign blende.
[2] At average of sales of 60° B. acid.

ZINC DUST

Production of zinc dust in 1951 totaled 31,695 tons, a 10-percent increase over 1950 output. Zinc powder and blue powder are not included in Bureau of Mines production totals; the zinc dust included is restricted to commercial grades that comply with close specifications as to percentage of unoxidized metal, evenness of grading, and fineness

Digitized by Google

of particles. The zinc content of the dust produced in 1951 ranged from 95.00 to 99.70 percent and averaged 97.71 percent. Shipments of zinc dust, which totaled 31,054 tons—590 tons of which went to foreign countries—were slightly below production. Producers' stocks of zinc dust rose from 424 tons (revised) at the beginning of the year to 726 tons at the end.

The average price of zinc dust shipped to domestic consumers in 1951 was 21.2 cents a pound compared with 16.6 cents in 1950. The raw materials used to manufacture zinc dust are reviewed in the Secondary Metals—Nonferrous chapter of this volume. Most of the production is from zinc scrap (principally galvanizers' dross), but some is recovered from zinc ore, slab zinc, and as a byproduct of zinc refining.

TABLE 10.—Zinc dust [1] produced in the United States, 1942–46 (average) and 1947–51

Year	Short tons	Value		Year	Short tons	Value	
		Total	Average per pound			Total	Average per pound
1942–46 (average)	25,951	$5,346,423	$0.103	1949	22,776	$6,195,072	$0.136

1948	32,217	10,051,704	.156	1951	31,695	13,438,680	.212

[1] All produced by distillation.

ZINC PIGMENTS AND SALTS

The principal zinc pigments are zinc oxide and lithopone, and the principal salts are the chloride and sulfate. These products are manufactured from various zinc-bearing materials, including ore, metal, scrap, and residues. Details of the production of zinc pigments and salts are given in the Lead and Zinc Pigments and Zinc Salts chapter of this volume.

CONSUMPTION AND USES

According to reports from approximately 700 plants, 933,971 tons of slab zinc was put into process in 1951, 3 percent less than the record quantity of 1950. Receipts at consumers' plants in 1951 were 919,617 tons.

Galvanizing continued to be the largest field of zinc use in 1951, accounting for 43 percent of the total consumption of slab zinc; the quantity so consumed during the year was 9 percent less than the record high used in 1950. The use of slab zinc for zinc-base alloys (largely die castings), the second largest application of the metal, was the highest on record, exceeding the previous peak established in 1950 by 2 percent. Consumption of slab zinc for the manufacture of brass products increased 3 percent over 1950 to the highest point since 1946 but was well below the average of the World War II period. The low level of slab zinc consumption in brass in the postwar period is attributed to the abnormal flow of brass scrap to the mills.

[1] Excludes some small consumers.
[2] Includes zinc used in electrogalvanizing and electroplating, but excludes sherardizing.
[3] Includes zinc used in making zinc dust, bronze powder, alloys, chemicals, castings, and miscellaneous uses not elsewhere mentioned.
[4] Includes 3,577 tons of remelt zinc in 1947, 3,141 tons in 1948, 2,394 tons in 1949, 3,035 tons in 1950, and 4,505 tons in 1951.

The quantity of slab zinc consumed for rolled products in 1951 decreased 6 percent from the 1950 figure. In addition to slab zinc, the rolling mills remelt and reroll the metallic scrap produced from their fabricating operations. The scrap so treated in 1951 amounted to 11,627 tons compared with 13,841 tons in 1950. Purchased zinc scrap, in the form of zinc clippings, old zinc scrap, and engravers' plates, totaling 3,799 tons, was melted and rolled in 1951 (4,516 tons in 1950). Production of rolled zinc from both slab zinc and purchased scrap was 66,088 tons, a decrease of 6 percent from the 1950 total. Inventories of rolled zinc were 2,006 tons on December 31, 1951, compared with 1,411 tons (revised figure) on the same date in 1950. In addition to the actual shipments of 52,557 tons of rolled zinc in 1951, the rolling mills processed 24,563 tons of rolled zinc (including that which was remelted and rerolled) in manufacturing 13,473 tons of semifabricated and finished products.

TABLE 12.—Rolled zinc produced and quantity available for consumption in the United States, 1950–51

	1950			1951		
	Short tons	Value		Short tons	Value	
		Total	Average per pound		Total	Average per pound
Production:						
Sheet zinc not over 0.1 inch thick	18,436	$8,805,695	$0.239	17,535	$10,536,341	$0.300
Boiler plate and sheets over 0.1 inch thick	926	377,778	.204	2,211	1,112,648	.252
Strip and ribbon zinc [1]	49,167	18,335,444	.186	44,713	21,057,114	.236
Foil, rod, and wire	1,546	849,581	.275	1,629	1,014,227	.311
Total rolled zinc	70,075	28,368,498	.202	66,088	33,720,330	.255
Imports	211	92,862	.220	149	84,406	.283
Exports	3,290	1,496,158	.227	4,868	3,126,189	.321
Available for consumption	67,652			60,774		
Value of slab zinc (all grades)			.142			.182
Value added by rolling			.060			.073

[1] Figures represent net production. In addition 13,841 tons of strip and ribbon zinc in 1950 and 11,627 tons in 1951 were rerolled from scrap originating in fabricating plants operated in connection with zinc rolling mills.

Table 13 shows the six commercial grades of refined slab zinc and purchased remelt spelter consumed by the various industries in 1951. Of the 933,971 tons of domestic and foreign zinc consumed, 41 percent was Prime Western, 38 percent Special High Grade, and 14 percent Regular High Grade, compared with 44, 34, and 14 percent, respectively, in 1950. All grades of zinc were used for galvanizing. Prime Western was the principal grade used in the hot-dip process, the higher grades being used chiefly for electrogalvanizing. Rigid specifications in brass manufacture necessitate the use of high-purity metal, 76 percent of the total used in this industry in 1951 being of the 2 highest grades.

TABLE 13.—Consumption of slab zinc in the United States in 1951, by grade and industry, in short tons

Industry	Special High Grade	Regular High Grade	Intermediate	Brass Special	Selected	Prime Western	Remelt	Total
Galvanizers	14,491	19,683	10,615	12,033	269	340,699	2,489	400,279

CONSUMPTION OF SLAB ZINC BY GEOGRAPHIC AREAS [1]

The geography of slab zinc consumption is available in detail only since 1940. During the 12-year period through 1951, substantial shifts occurred, largely as a result of conversion to war production in 1940–41 and reconversion to peacetime consumption in 1945–46. The distribution of slab-zinc consumption by geographic divisions and States, both total and for individual uses, is shown in tables 14 to 20.

Consumption of Slab Zinc for All Uses.—During the period 1940–51 Illinois ranked first among the 42 zinc-consuming States and the District of Columbia, with an annual average of 139,376 tons. Since 1945 Ohio has been in second place. Connecticut, the second largest consuming State during the World War II period owing to the large quantities of zinc consumed in the brass plants of the State, has since dropped to fourth place. Pennsylvania has held either second or third place since 1940. The greatest concentration of slab-zinc consumption is in the region comprising Illinois, Indiana, Michigan, Ohio, and Wisconsin. This area, which has consistently ranked first in zinc consumption since 1940, uses nearly half the total quantity of slab zinc consumed annually in the United States. The region of least consumption is the Mountain States, including Arizona, Colorado, Idaho, Nevada, New Mexico, and Utah, which have consumed less than 0.3 percent of the total.

Consumption of Slab Zinc for Galvanizing.—The iron and steel industry, the largest consumer of slab zinc, uses it for galvanizing or rustproofing sheets, wire, tube and pipes, building and pole-line hardware, railway-signal equipment, chains, bolts, screws, and a multitude of other items. The principal iron- and steel-producing States are thus also the principal consumers of zinc for galvanizing. From 1940 through 1943 Pennsylvania ranked first among the 34 States that consumed zinc for this purpose. In 1944 Ohio displaced Pennsylvania and retained the top position in the succeeding years through 1951. The greatest concentration of zinc consumption for galvanizing is in the region comprising Illinois, Indiana, Ohio, and Pennsylvania, which consumed 62 percent of the average annual domestic total for this use in 1940–45. In 1946 total zinc used for galvanzing in these States rose to 65 percent but declined to 63 percent in 1947 and 1948, 61 percent in 1949, 59 percent in 1950, and 58 percent in 1951.

[1] This section is based partly on a detailed study by Ransome, Alfred L., Consumption of Slab Zinc in the United States by Industries, Grades, and Geographic Divisions, 1940–45: Bureau of Mines Inf. Circ. 7450, 1948, 30 pp.

[2] Quantity withheld to avoid disclosure of individual company operations.
[3] Includes States not individually shown (footnote reference 2).

Consumption of Slab Zinc for Brass Products.—From 1940 through 1951 Connecticut has ranked first among the States consuming slab zinc for brass products; but, owing to the wartime demand for brass and the construction of new plant facilities, there has been some change in the rank of the other leading States. In 1940 Michigan was in second place, followed by New York, Illinois, Ohio, and Pennsylvania, whereas in 1951 Illinois ranked second, with Michigan in third place, followed by Ohio, New York, and Wisconsin.

Consumption of Slab Zinc for Zinc-Base Alloys.—The automobile industry is the largest user of zinc-base alloys, principally for die-cast parts and assemblies, such as fuel pumps, carburetors, radiator grilles, windshield-wiper motors, and a wide variety of both interior and exterior hardware. Thus the region embracing Illinois, Indiana, Michigan, Ohio, and Wisconsin, in which the automobile industry is centered, is the area of greatest concentration of slab-zinc consumption for zinc-base alloys. Over 64 percent of the zinc for die casting and other zinc-base alloy uses in 1951 was consumed in this region.

Consumption of Slab Zinc for Rolled Zinc.—During the period 1940–51, although the quantity of slab zinc consumed for rolled zinc changed widely, the geographic pattern of consumption and rank of the consuming States varied little. Illinois and Indiana ranked first and second, respectively, except in 1951, when Pennsylvania moved into second place and Indiana dropped to third.

TABLE 18.—Consumption of slab zinc for rolled zinc in the United States, 1944–48 (average) and 1949–51, by States

State	Geographic division	1944–48 (average)		1949		1950		1951

STOCKS

Producers' Stocks.—Inventories of slab zinc at producers' plants were more than doubled during 1951 but were still relatively low, inasmuch as ending stocks in 1950 had been the lowest since 1925.

TABLE 21.—Stocks of zinc at zinc-reduction plants in the United States at end of year, 1947–51, in short tons

	1947	1948	1949	1950	1951
At primary reduction plants	67,046	19,179	90,710	[1] 7,948	21,344
At secondary distilling plants	1,601	1,669	3,511	[1] 936	637
Total	68,647	20,848	94,221	8,884	21,981

[1] Revised figure.

Consumers' Stocks.—On December 31, 1951, consumers' stocks of slab zinc were 50,071 tons compared with 64,206 tons at the beginning of the year. At the average monthly rate of consumption in 1951, consumers' stocks on hand on December 31 were approximately 19 days' requirements.

TABLE 22.—Consumers' stocks of slab zinc at plants at the beginning and end of 1951, by industries, in short tons

Date	Galvanizers	Brass mills [1]	Die casters [2]	Zinc rolling mills	Oxide plants	Others	Total
Dec. 31:							
1950	[3] 36,296	[3] 8,466	[3] 14,644	3,190	[3] 383	[3] 1,227	[3] [4] 64,206
1951	20,110	14,717	10,137	3,538	320	1,249	[4] 50,071

[1] Includes brass mills, brass ingot makers, and brass products.
[2] Includes producers of zinc-base die castings, zinc-alloy dies, and zinc-alloy rods.
[3] Revised figure.
[4] Stocks on Dec. 31, 1950, and 1951, exclude 629 (revised figure) and 410 tons, respectively, of remelt spelter.

PRICES

The price of zinc was controlled by the Office of Price Stabilization during 1951. Ceiling prices were established for zinc on January 26, 1951, at the highest price (for each seller) at which sales were made between December 19, 1950, and January 25, 1951. Thus a number of ceiling prices were maintained. The bulk of zinc sales, however, were based on the 17.50-cent-per-pound quotation for Prime Western-grade slab zinc at East St. Louis. The 17.50-cent price remained in effect until October 2, 1951, when the Office of Price Stabilization permitted a rise of 2 cents per pound. No further change in price occurred in 1951.

The official London price of £151 per long ton of zinc (equivalent to 18.88 cents per pound computed on the 280.00-cent per £ base), established by the British Ministry of Supply on October 4, 1950, was in effect until April 1, 1951, when the Ministry increased the price to £160 (20.00 cents). The price was raised by £30 on July 14 to £190 (23.75 cents), at which level it remained for the remainder of the year. (During the latter half of 1951 sterling exchange rates varied between 278.63 and 280.00 cents per £, hence dollar-equivalent prices varied slightly from the £190 or 23.75-cent level).

FOREIGN TRADE [4]

Imports.—Total imports (general imports) of zinc in ores and concentrates in 1951 increased 9 percent over 1950. Of the 303,038 tons imported, 47 percent came from Mexico, 32 percent from Canada, and 10 percent from Peru. The remaining 11 percent was largely from Bolivia, Guatemala, Argentina, Spain, Australia, the Union of South Africa, Yugoslavia, and Chile.

Slab-zinc imports declined to 87,983 tons or 44 percent less than the quantity imported in 1950. Canada supplied nearly 97 percent of the total. The remaning 3 percent came principally from Norway, Mexico, Belgium-Luxembourg, French Morocco, and the Netherlands.

TABLE 26.—Zinc imported into the United States, in ores, blocks, pigs, or slabs, 1949–51, by countries, in short tons [1]

1949	109,535	11,748,199	125,564	29,340,620	32	8,144	3,732	558,702	17	4,397	41,660,062
1950	[4] 237,564	[4] 24,313,625	[4] 155,332	[4] 38,759,435	211	92,862	[4] 2,862	[4] 688,176	472	80,564	[4] 63,934,662
1951	198,373	27,043,611	87,983	31,088,382	149	84,406	6,603	284,030	154	74,362	58,574,791

[1] Excludes imports for manufacture in bond and export, which are classified as "imports for consumption" by the U. S. Department of Commerce.
[2] Includes dross and skimmings as follows: 1947—4,391 tons, $353,415; 1948—8,637 tons, $873,099; 1949—2,668 tons, $335,283; 1950—1,229 tons, $186,748; 1951—6,547 tons, $242,998.
[3] In addition, manufactures of zinc were imported as follows: 1947—$4,429; 1948—$16,056; 1949—$2,583; 1950—$142,369; 1951—$51,700.
[4] Revised figure.

Exports.—The value of zinc ores, concentrates, and metal exported amounted to $22,018,441 in 1951 compared with $7,414,904 in 1950. In addition to the items shown in tables 28 and 29, considerable zinc is exported each year in brass, pigments, chemicals, and galvanized iron and steel. Export data on zinc pigments and chemicals are given in the Lead and Zinc Pigments and Zinc Salts chapter of this volume.

Exports of slab zinc in 1951 totaled 36,510 tons, almost 3 times as much as the quantity exported in 1950. The United Kingdom, India, and Brazil were the chief importers, receiving 55, 13, and 11 percent, respectively, of the total. Table 29 contains details of exports of zinc slab and sheet.

[1] Less than 0.5 ton.

Tariff.—Following agreements at the Geneva Trade Conference of 1947 import duties of ¾ cent per pound on zinc-bearing ores and concentrates (zinc content) and ⅞ cent per pound on zinc in blocks, pigs, slabs, and dust were established, effective January 1948. These duties remain in effect until June 6, 1951, when the tariff was reduced to 7/10 cents per pound on ore and 7/10 cent per pound on zinc metal.

Zirconium

By A. J. Kauffman, Jr.

GENERAL SUMMARY

ZIRCONIUM has come recently to the attention of metallurgists and engineers as a structural metal having tremendous potentialities. Because it is highly resistant to heat and corrosion, zirconium is a promising structural material for nuclear reactors and may play an important part in harnessing atomic power. It is also of great interest to engineers seeking a metal that can withstand the high temperatures in the combustion chambers of jet engines and superrockets.

DOMESTIC PRODUCTION

Mine Production.—Domestic output of zircon continued to increase during 1951, surpassing the record production of 1950 by more than 50 percent. Principal producers were again the Rutile Mining Co. of Florida, South Jacksonville, Fla., and Humphreys Gold Corp., Starke, Fla. The Florida Ore Processing Co., Melbourne, Fla., improved its facilities and was expected to increase production. Humphreys Gold Corp. at Starke, Fla., again accounted for the increased domestic production. This company operates the titanium-mineral concentrator of E. I. duPont de Nemours & Co. on a contract basis; the zircon is obtained by treating the concentrator rejects.

Accumulation of zircon-rich concentrator rejects at Boise, Idaho, continued as a consequence of the monazite recovery operation there.

Refinery Production.—The principal producers of zirconium refractories, compounds, metal, and alloys are listed below:

Producer and plant location:	*Products*
F. W. Berk & Co., Woodbridge, N. J.	Zirconium compounds.
De Rewal International Rare Metals Co., Philadelphia 5, Pa.	Low-hafnium zirconium oxide and metal powder; zirconium compounds.
Electro Metallurgical Co., Division of Union Carbide & Carbon Corp., New York 17, N. Y.	Zirconium alloys.
Foote Mineral Co., Philadelphia, Pa.	Zirconium metal, compounds, and ground zircon.
Kawecki Chemical Co., Boyertown, Pa.	Potassium fluozirconate.
The Massillon Refractories Co., Massillon, Ohio.	Zircon crucibles, brick, and special shapes.
Metal Hydrides Inc., Beverly, Mass.	Zirconium metal powder, zirconium hydride, and various alloys.
Norton Co., Worcester, Mass.	Fused stabilized zirconia refractories.

Digitized by Google

Rohm & Haas Co., Philadelphia 5, Pa.	Zirconium tanning agent.
Stauffer Chemical Co., New York 17, N. Y.	Zirconium tetrachloride.
Chas. Taylor & Sons (subsidiary of National Lead Co.), Cincinnati, Ohio.	Special zirconia refractories.
Titanium Alloy Manufacturing Division of National Lead Co., Niagara Falls, N. Y.	Zirconium metal sponge and briquets, alloys, compounds, ground zircon, and stabilized zirconia refractories.
Westinghouse Electric Corp., Pittsburgh, Pa.	Zirconium metal, experimentally.
Bureau of Mines, Albany, Oreg.	Zirconium metal.

CONSUMPTION AND USES

Annual domestic requirements for zirconium minerals are estimated to be 20,000 to 30,000 tons. According to information furnished by the principal zircon dealers, the distribution, by use, for 1951 was as follows: Porcelain enamel, 7 percent; pottery, 7 percent; electrical and chemical porcelain, 3 percent; refractories, 45 percent; glass, 1 percent; metals and alloys, 7 percent; foundry facings, 19 percent; miscellaneous, 11 percent.

Zircon is used as an acid-type refractory because its resistance to abrasion is coupled with a striking resistance to attack by certain molten metals, acidic chemicals, slags, and glasses. Zircon refractories are used mainly in aluminum-melting furnaces because they are not wetted by aluminum metal, dross, or slag. Zircon is used as a foundry and molding sand primarily because the mineral is not wetted by molten iron; as a consequence, zircon grains will not adhere to the outer surface of castings. Zirconia (chemically prepared zirconium dioxide), when stabilized with magnesia or lime is an important refractory.[1] Baddeleyite, naturally occurring zirconium dioxide, is used in the manufacture of refractories, whiteware bodies, and glass furnace linings.

Zirconium chemicals are increasingly important.

Ductile zirconium metal is becoming available in ever-increasing amounts;[2] the bulk of the metal produced, however, is used by Government agencies. Zirconium is useful in the construction of nuclear reactors. Its desirable properties are corrosion resistance, ductility strength, and low rate of neutron absorption.[3] The resistance to corrosion by acids and alkalies suggests important uses in the chemical industry for applications such as a material for tank linings, pipes, valves, and immersion heaters. Its high tensile strength and resistance to attack and discoloration by iodine, mercury salts, and high-temperature sterilization make it well suited for surgical instruments, suture wire, bone screws, and cranial plates.

Magnesium-cerium-zirconium alloys have a combination of good casting qualities and good mechanical properties at ordinary and

elevated temperatures, which make them attractive for some important lightweight stressed components of engines for which magnesium-base materials have been unsuitable in the past. Studies have been made of other alloys also.

STOCKS

Inventories of zircon concentrates (65 percent ZrO_2), including some baddeleyite held by industry, totaled about 7,515 short tons at the close of 1951, compared with 8,100 short tons for the 1950 year end. Mixed zircon-rutile stocks were reduced to 723 short tons (about 629 tons zircon), compared with 2,400 short tons (about 1,500 tons zircon) at the end of 1950.

PRICES

E&MJ Metal and Mineral Markets quoted zircon concentrates (65 percent ZrO_2), c. i. f. Atlantic ports, at \$50–\$55 per ton at the beginning of 1951; \$60–\$70, April 26; \$70–\$72, November 8; \$47–\$52, December 13; and \$47–\$50, December 20.

Quotations for zirconium-metal powder (ductile metal cannot be made directly from this material) of \$7–\$8 per pound, depending upon quantity, remained unchanged during 1951. Ductile zirconium metal made by the iodide-reduction process and fabricated forms from that stock produced by the Foote Mineral Co. were quoted as follows: Zirconium crystal bar at \$90 per pound in quantities less than 100 pounds; zirconium wire, 0.070- to 0.003-inch diameter, \$327 to \$793 per kilogram; zirconium swaged rod, 7/16- to 5/64-inch diameter, \$200 to \$210 per kilogram; and zirconium sheet, 0.015- to 0.002-inch thick, \$289 to \$450 per kilogram. In November 1951, Titanium Alloy Manufacturing Division, National Lead Co., producers of ductile zirconium by the magnesium-reduction process, quoted the following prices for the ductile metal and forms fabricated from that stock: Zirconium-metal sponge and briquets, \$10 per pound; hot-rolled plate and bars at a base price of \$27 per pound; hot-rolled strip, \$28 per pound; cold-rolled strip, \$35 per pound; and cold-drawn wire, \$32.50–\$42.50 per pound, depending upon size. Zirconium tetrachloride, the starting material for the production of ductile zirconium, was quoted at \$0.34 per pound, f. o. b. Niagara Falls, N. Y., in lots of 1 ton to a carload.

According to Iron Age, zirconium-ferrosilicon alloys, 12–15 percent (39–43 percent Si) and 35–40 percent (47–52 percent Si), were \$0.07 and \$0.21, respectively, per pound of alloy, f. o. b. plant, carlots, in January 1951 and remained unchanged throughout the year.

The Oil, Paint and Drug Reporter quoted zirconium compounds, per pound, in carlots, as follows: In January acetate was quoted at \$0.21¼; carbonate at \$0.31½; hydride, \$7; nitrate at \$1.75; and oxide, \$1.50. Acetate increased to \$0.26½ in March and continued at that level throughout the year; the price of carbonate remained unchanged; hydride increased to \$12 during the latter part of October and then held steady; nitrate increased to \$2.10 in March and to \$4.50 in October, and thereafter was unchanged; oxide held at \$1.50 throughout the year.

FOREIGN TRADE [4]

Imports of zirconium ore into the United States during 1951 came from Australia and Brazil.

Exports of zircon concentrates in 1951, principally to Canada, totaled 370 short tons valued at $36,548. Zirconium metal and alloy exports increased to 83,461 pounds, valued at $49,675. Canada and France were the major recipients.

TABLE 1.—Zirconium ore (concentrates) imported for consumption in the United States, 1947–51, by countries, in short tons [1]

[U. S. Department of Commerce]

Year	Australia [2]	Brazil	Canada	India	Total	
					Short tons	Value
1947	21,894	4,619	2	4,181	30,696	$891,161
1948	14,320	3,553	2	279	18,154	571,161
1949	18,839	1,994	----	----	20,833	636,529
1950	15,988	697	141	----	16,826	431,107
1951	25,208	2,084	----	----	27,292	664,428

[1] Concentrates from Australia are zircon or mixed zircon-rutile-ilmenite, and those from Brazil are baddeleyite or zircon. All other imports are zircon.

[2] Imports of zircon, rutile, and ilmenite from Australia until early 1948 were largely in the form of mixed concentrates. These mixed concentrates are classified by the U. S. Department of Commerce arbitrarily as "zirconium ore," "rutile," or "ilmenite." Total zircon content of the "zirconium ore" (as shown in this table) and of the "rutile" and "ilmenite" concentrates (*see* Titanium chapter) are estimated as follows: 1947, 22,727 tons; 1948, 13,873 tons; 1949, 14,623 tons; 1950, 15,098 tons; and 1951, 24,577 tons.

TECHNOLOGY

The important role ductile zirconium is playing in the nuclear-reactor development program was indicated in the Atomic Energy Commission press release dated March 6, 1951, which announced plans to encourage wider industrial participation in the manufacture of high-purity zirconium metal.

A brief account of the development of ductile zirconium follows:

In 1925 the Netherlands investigators, A. E. Van Arkel and J. H. deBoer, produced the pure metal while working at the University of Leyden.[5] The deBoer process was modified by the Philips Lamp Co., Eindhoven, Netherlands, and put into commercial operation. The Foote Mineral Co., Philadelphia, Pa., further modified the process and for many years was the only producer of ductile zirconium metal in this country. The Foote company has been instrumental in engineering the production of iodide-process zirconium from 4-inch-diameter glass bulbs to 24-inch metal deposition tubes.[6]

The major producer of ductile zirconium is the Northwest Electrodevelopment Laboratory, Bureau of Mines, Albany, Oreg. Dr. William J. Kroll and his coworkers at Albany developed the magnesium-reduction method, a multistep batch process for the production of ductile zirconium. The Bureau of Mines was encouraged in this

[4] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Digitized by Google

work by the Bureau of Ships, Navy Department, and by the Atomic Energy Commission because of their long-range interests in ductile zirconium.

The steps involved in the magnesium-reduction method are: (1) Reaction of zircon and carbon to form zirconium carbide, more recently by the treatment of purified zirconium oxide and carbon in a graphite resistor furnace; (2) chlorination of the carbide to form crude zirconium tetrachloride; (3) purification of the crude chloride; (4) reduction of the purified chloride by molten magnesium to form zirconium sponge; and (5) melting of the sponge to form ingots of ductile zirconium metal. Each batch produces about 150 pounds of metal sponge from 420 pounds of raw chloride; 100 pounds of magnesium metal is used for the reduction. Expansion of plant facilities was underway in 1951 to increase production to at least 10,000 pounds of zirconium sponge per month.[7]

Titanium Alloy Manufacturing Division, National Lead Co., Niagara Falls, N. Y., produced ductile zirconium in 1951 using the Kroll magnesium-reduction method.

Westinghouse Electric Corp. investigated a process for reducing zirconium dioxide with calcium metal.

Much of the ductile zirconium metal produced before 1951 contained varying amounts of hafnium, which occurs in nature associated with zirconium minerals; zircon, the most abundant source of the metal, contains about 2.5 percent hafnium. Hafnium and zirconium resemble each other in chemical behavior more than any other two elements. Due to this similarity, the first problem in preparing pure zirconium is to remove hafnium.[8] Hafnium metal is ductile, is resistant to corrosion, and has a high melting point. These properties suggest possible uses in the electronics industry for filament and cathode surfaces. The oxide and salts exhibit catalytic properties; the oxide and carbide are highly refractory and may find use in superrefractories for jet engines, nuclear reactors, and other high-temperature devices.

WORLD REVIEW

Australia.—For many years Australia has been the world's principal producer of zircon concentrates. Zircon-Rutile, Ltd., largest Australian zircon producer, reported an improved market for its products in 1950, a condition that apparently continued through 1951, as witnessed by the greatly increased exports to the United States.[9] Australian zircon producers, however, were reported also to be concerned about future outlets for their material because of the increased output of the Florida operations.[10]

Brazil.—Baddeleyite (zirconium dioxide) is found in large concentrations in the Pecos de Caldas area of the States of São Paulo and Minas Gerais, Brazil. Deposits of zircon are known in the States of Baía, Espírito Santo, and Rio de Janeiro.

Digitized by Google

Egypt.—Zircon is found in black sands of the Mediterranean coast around the mouths of the Rosetta and Damietta branches of the Nile. Production for 1942 and 1944 was 39 and 12 metric tons, respectively.

Germany (Eastern Zone).—The Geological Institute of the University of Rostock indicated that zirconium and titanium minerals would soon be recovered commercially from beach sands along the Baltic Sea coastline of Mecklenburg.[11]

Senegal (French West Africa).—Zircon-rich black sands occur near Rufisque. Production of zircon concentrates in 1949 amounted to 245 metric tons. Assistance was reported sought from the Economic Cooperation Administration in obtaining equipment to mine the deposits.[12]

Union of South Africa.—Attention has been given in recent years to the beach sands of Natal, notably in the vicinity of Durban. Heavy mineral concentrates from the sands reportedly contain 8 percent zircon.[13]

United Kingdom.—Annual zircon requirements of the United Kingdom were estimated at 5,000 to 7,000 tons per year.[14] According to reports, a plant for making a range of zirconium products was under construction by Goodlass Wall & Lead Industries, Ltd., at Newcastle-upon-Tyne; operations were expected to begin in 1951.

Minor Metals

By E. J. Carlson, A. J. Kauffman, Jr., H. D. Keiser, and Stanley Needleman[1]

CESIUM AND RUBIDIUM[2]

CESIUM and rubidium usually occur together in nature. Cesium is obtained chiefly from pollucite, a cesium-aluminum-sodium silicate mineral that contains 30 to 36 percent Cs_2O and about 3 percent Rb_2O. Pollucite occurs in pegmatites found in Maine, the Black Hills of South Dakota, South-West Africa, and the Union of South Africa. Rubidium is extracted commercially from the lithium-mica mineral, lepidolite. Some varieties of beryl that are particularly white contain as much as several percent of cesium and rubidium; these elements could be extracted economically from such beryl if the demand for them were sufficient.

Production.—Cesium and rubidium metals and compounds were produced in 1951 by DeRewal International Rare Metals Co., Philadelphia, Pa.; Maywood Chemical Works, Maywood, N. J. (Cs metal, Cs and Rb compounds); Fairmount Chemical Co., Newark N. J. (Cs and Rb metals and compounds); General Electric Co., Scotia, N. Y. (Cs metal); A. D. Mackay, Inc., New York, N. Y. (Cs and Rb metals and compounds); and Foote Mineral Co., Philadelphia, Pa. (Cs compounds). Harshaw Chemical Co., Cleveland, Ohio, produced synthetic optical crystals of cesium iodide for use in scintillator counters and optical devices.

Uses.—Cesium and rubidium are used principally in photoelectric cells as the active agents in the emission of electrons. Cesium is used in vapor lamps adapted for infrared signalling uses by the military. Cesium and rubidium are used as catalysts in the polymerization of certain resin materials to yield a durable protective coating. It was reported in 1951 that cesium–137, a gamma-emitting fission product with a half life of 33 years, might rival cobalt–60 in radiation therapy. Rb–87 is a naturally occurring radioactive isotope of rubidium that emits beta radiation.

Prices.—Chemically pure cesium and rubidium metal, double-distilled, in sealed glass ampoules, were quoted in 1951 at $4–$5 and $4.50–$5.50 per gram, respectively, depending on quantity.

---

[1] Unless otherwise indicated, figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce. Beryllium and zirconium, included in the 1950 Minor Metals chapter, are reviewed in separate chapters in this volume.

Technology.—A method was developed of extracting cesium from ore and mixtures of metals.[3] Methods for accurate quantitative analysis of rubidium in lepidolite by spectrochemical procedures were described, using potassium as an internal standard.[4]

World Review.—An output of about 100 tons of pollucite was reported in South-West Africa during 1946–51; 19 tons of this cesium ore (26–30 percent Cs_2O) and 11,090 tons of lepidolite (1.5 percent Rb_2O) were produced in 1951 from pegmatite deposits 18 miles south of Karabib. Several tons of pollucite was recovered as a byproduct of beryl mining in the Union of South Africa.

COLUMBIUM (NIOBIUM) AND TANTALUM[5]

To insure a dependable supply of columbium and tantalum, emphasis has been placed on the development of low-grade domestic deposits. As a result of the extensive monazite exploration program of the Bureau of Mines, under contract to the Atomic Energy Commission, substantial tonnages of columbite-tantalite have been found as constituents of black sands. Preliminary investigations by the Bureau of Mines, Federal Geological Survey, and Arkansas Geological Survey have disclosed appreciable quantities of columbium associated with the titanium minerals and bauxite in Pulaski and Saline Counties, Ark. Further mining and metallurgical research will be necessary before these metals can be assured in the quantities required by industry for the defense effort.

On March 19, 1951, the National Production Authority placed columbium and tantalum under defense allocation by an amendment to Order M–3. Columbium-bearing steels had been reserved for defense needs under Order M–3; subsequent amendments thereto limited the proportion of columbium that could be used in stainless steel. In December 1951 the National Production Authority issued Order M–80 permitting the use of columbium and tantalum in the manufacture of Class A and/or Class B products required by the Department of Defense or Atomic Energy programs. Certification by the Aircraft Production Resources Agency was required for columbium and tantalum alloys used in the aircraft program. Columbium-coated welding rod was classified as a columbium-bearing steel.

Mine Production.—Domestic mine shipments of columbite-tantalite concentrates during 1951 totaled 925 pounds. Principal producers were Beryllium Mining Co., Inc. (New Anniversary claims), Ohio City, Colo., and George C. Bland (Beecher Lode), Hill City, S. Dak. Small lots of columbite-tantalite concentrates produced during the year may have remained unsold.

Domestic Refiners.—Ferrocolumbium and ferrocolumbium-tantalum alloys were produced by the Electro Metallurgical Division, Union Carbide & Carbon Co., Niagara Falls, N. Y. Miscellaneous tantalum and columbium products were manufactured by Fansteel Metallurgical Corp., North Chicago, Ill. Kennametal, Inc., Latrobe, Pa., marketed "Kentanium," a carbide containing columbium and tantalum.

1951	[2]	[2]	[4] 925	1,528

[1] Principally microlite.
[2] Bureau of Mines not at liberty to publish.
[3] Columbite and tantalite production not differentiated and given under tantalum concentrates.
[4] Tantalite-columbite.

Uses.—High-temperature alloys, important to jet engines and gas turbines, compete with heat- and corrosion-resistant stainless steels for the world's limited supply of columbium, an alloying agent that has acquired strategic importance in the last decade. Columbium is an important additive to the supertemperature alloys; when used in concentrations of 1 to 5 percent, it maintains strength at high temperatures and provides good resistance to creep. The principal use of columbium in steels is as a carbide stabilizer; it decreases susceptibility to intergranular corrosion, improves weldability, and increases creep and impact strength. Columbium is becoming increasingly important as a constituent of ferrous and nonferrous alloys being developed for parts exposed to high temperatures generated in jet engines and gas turbines. Chromium-nickel-columbium steel has strength properties adequate for applications such as rotor forgings, blades, and tubes used in gas turbines.[6] A report was published in 1951 reviewing the effects of small additions of columbium to certain high-temperature jet engine alloys,[7] and the titanium-columbium system was studied.[8] Kentanium, the new columbium-tantalum carbide, is used in the aircraft industry.

Tantalum, a readily formative and highly corrosion-resistant metal, is used principally in the pure form. Considerable quantities are used in the chemical industries for heat exchangers, condensers, absorption towers, and other devices subject to corrosive attack. The metal is a structural material suitable for use with hydrogen peroxide under a wide range of conditions as far as peroxide stability and resistance to corrosion are concerned. Research continued on tantalum for use in capacitors. Tantalum metal is used in surgery for cranial plates and sutures and in electronics as a structural component in many types of vacuum tubes. The carbide of tantalum is used for cutting tools, dies, and other wear-resisting parts. Tantalum oxide is an important component of silica-free optical glass.

Digitized by Google

Tantalum can be substituted for columbium in the high-temperature alloys on a point for point basis, providing equal strength and creep resistance. The corrosion resistance of tantalum-molybdenum alloys was the subject of an important investigation.[9] Improved ductility and reduction in tendency to air-harden are imparted to chromium stainless steels by additions of columbium and tantalum.

Patents issued during 1951 included a method for making a tantalum anode for gas-filled tubes [10] and a method for drawing filled tantalum tubes.[11]

Prices.—Metal Bulletin (London) quotations on columbite, 50–55 percent combined pentoxides (Cb_2O_5 plus Ta_2O_5), per unit, c. i. f. Atlantic ports, opened the year at 250s.–260s. and on January 19 was stabilized at 256s., with no further changes during 1951. E&MJ Metal and Mineral Markets quotations for tantalum ore, 55–60 percent Ta_2O_5, were unchanged during the year at $2–$2.50 per pound. Columbium-metal powder held steady at $62.75 per pound, and tantalum-metal powder was offered at $33.50. Prices of columbium metal have remained unchanged since 1948, being quoted at $280 per kilogram for rod and $250 for sheet. Similarly, tantalum rod was quoted at $160.60 and sheet at $143. Ferrocolumbium and ferro-columbium-tantalum were quoted throughout 1951 at $4.90 and $2.75 per pound of contained columbium, respectively.

Foreign Trade.—During 1951 imports of columbite ore into the United States declined about 10 percent compared with 1950, although receipts from Nigeria increased slightly. The bulk of the United States supply continued to be low-grade columbite concentrates. Tantalite imports decreased during the year.

Other imports, all from the United Kingdom, included: Columbium alloys, principally ferrocolumbium, 63,622 pounds, valued at $175,778; columbium metal, 6,178 pounds, valued at $18,806; and tantalum metal, 5,750 pounds, valued at $8,646.

TABLE 2.—Columbium and tantalum ores (columbite and tantalite concentrates) imported for consumption in the United States, 1949–51, by countries, in pounds

[U. S. Department of Commerce]

Country	Columbium ore			Tantalum ore		
	1949	1950	1951	1949	1950	1951
Australia						1,467
Belgian Congo	198,585	400,868	177,273	38,086	211,433	210,402

Digitized by Google

The United States exported 41 pounds of tantalum ore, valued at $2,221, to the United Kingdom. No columbium ore was exported. Exports of columbium metal and alloys, principally to the United Kingdom, totaled 42 pounds, valued at $2,646; exports of tantalum metal and alloys totaled 1,676 pounds, valued at $74,814; principal recipients were United Kingdom, Sweden, France, Germany, and Italy.

WORLD REVIEW

Angola.—Large deposits of columbite-tantalite have been discovered in the Lobito area of Angola.

Argentina.—Tantalite occurs at Salta, near the Bolivian border, and in the San Louis Province. The deposits at Salta are the more important.

Belgian Congo.—Legislative Ordinance 33/99, dated March 12, 1951, removed columbite-tantalite minerals from the schedule of export taxes; this was done in an effort to stimulate operations of marginal deposits.

Geomines, at Manono, continued to be the principal columbite-tantalite producer in the country. Expansion of production was expected as a result of financial assistance supplied by the Foreign Expansion Division, Defense Materials Procurement Agency, formerly Economic Cooperation Administration.

Columbite-tantalite reserves in Congo and Ruanda-Urundi have been estimated at about 22,500 metric tons. The Somuki mine at Mouye, Ruanda-Urundi, resumed production, and the Buranga mine at Minetain, increased its output. Extensive prospecting in Ruanda-Urundi took place in certain areas of Mugendo, Gisitwe, Corem, and Runyankezi.

Canada.—Interest was shown in a deposit containing a small concentration of tantalite at Ross Lake, northeast of Yellowknife, Northwest Territory. Tantalum Refining & Mining Corp. of America, Ltd., conducted beneficiation studies which suggested further investigation.

French Cameroons.—The possibility of recovering columbite-tantalite as a byproduct of tin mining at Mayo Darle was investigated. Occurrences of columbite-tantalite have been found at Betare-Oya, on a tributary of the Lom River; on a tributary of the Mba River; and near the town of Dschang on the British Cameroons frontier.

French Equatorial Africa.—Several promising deposits were investigated in the Mayombe region of Moyen Congo. This area had a record of past production.

Malaya.—About 15 tons of columbite-tantalite concentrates was produced between 1945–51 as a byproduct of gold mining at Mayoko, in Moyen Congo. Malayan output of columbite for 1951 was about 25 tons; the concentrate was obtained as a byproduct of tin mining in the State of Kedah. Alluvial deposits of columbite-tantalite were investigated at Bakri near Muar on the west coast of the State of Johore and at Semiling in the northern part of the State of Kedah.

Mozambique.—About 92,550 kilograms of samarskite (an iron-calcium columbate-tantalate containing uranium and rare-earth elements) was produced in the Tete district of Mozambique. Shipments were made to France and the United Kingdom.

[1] This table and table 4 include a number of revisions of figures published in previous minor metals chapters. Concentrates produced in Argentina, Belgian Congo, French Equatorial Africa, and Mozambique are frequently termed "columbite-tantalite," this designation being applied because, in general, their composition (Cb_2O_5 Ta_2O_5) lies in an intermediate range, neither Cb_2O_5 nor Ta_2O_5 being strongly predominant. In tabulating production of columbite and tantalite, all output designated "columbite-tantalite" has arbitrarily been placed in this table. Concentrates imported into the United States are designated specifically as either columbite or tantalite, this classification sometimes being arbitrary; therefore discrepancies between figures in the columbite and tantalite production tables and United States import tables for these minerals should be viewed accordingly. In addition to countries shown, Bolivia reportedly exported 1,034 pounds in 1945, 6,834 pounds in 1946, and 1,043 pounds in 1951; production of columbite in Madagascar has been reported in 1945, 22 pounds and in 1951, 8,598 pounds; production in Malaya during the Japanese occupation was estimated at about 10,000 pounds; in 1950, 17,920 pounds; and in 1951, 56,000 pounds; Portugal exported columbite-tantalite concentrates in 1950, 3,009 pounds and in 1951, 4,526 pounds.

[2] Estimated average Cb_2O_5 content of concentrates.

[3] Exports.

[4] Data not available.

[5] Columbite-tantalite concentrates.

[6] Columbite and tantalite production in the United States not always differentiated; *see* table 4, on tantalite.

[7] Tin-columbite-tantalite concentrates, columbite-tantalite content unspecified, produced as follows: 1938, 20,066 pounds; 1939, 8,014 pounds; 1940, 1,546 pounds; 1943, 15,700 pounds; 1947, 329 pounds; 1948, 210 pounds.

[8] United States imports.

[9] Contained in 17,687 pounds mixed concentrates in 1945; in 7,706 pounds in 1946; in 3,651 pounds in 1947; in 3,203 pounds in 1948.

[10] In addition, tin-columbite-tantalite concentrates were produced as follows: 1947, 597,555 pounds, columbite-tantalite content unspecified; 1948, 1,148,050 pounds; 1949, 1,944,810 pounds; 1950, 2,431,674 pounds; 1951, 2,597,019 pounds (columbite-tantalite content averaging about 10 percent for 1948–51).

[11] In addition to figure shown, 204,036 pounds of samarskite was produced.

[1] *See* table 3, footnote 1. United States imports show 98 pounds tantalite received from Anglo-Egyptian Sudan in 1944; 700 pounds from Canada in 1944; and 1,805 pounds and 2,442 pounds from India in 1943 and 1944, respectively.
[2] Exports.
[3] Prior to 1941, concentrates were designated as "tantalite-columbite", however, in composition, Ta_2O_5 was strongly predominant over Cb_2O_5, therefore, these concentrates have been tabulated in this table rather than table 3, on columbite. From 1941 to 1948, inclusive, tantalite and columbite are differentiated.
[4] Data not available.
[5] *See also* table 3, on columbite.
[6] In addition, tin-tantalite-columbite concentrates, unspecified tantalite-columbite content, produced as follows: 1936, 1,165 pounds; 1937, 1,322 pounds; 1938, 1,366 pounds; 1940, 1,456 pounds; 1941, 370 pounds; 1942, 161 pounds; 1943, 560 pounds; 1944, 2,000 pounds.
[7] Principally microlite.
[8] Includes bismutotantalite as follows: 1944, 6,720 pounds; 1945, 670 pounds. Footnotes 2 and 5, above, also apply.
[9] Sales and exports.
[10] Tantalite-columbite.

Nigeria.—Production of columbite was adversely affected by lack of rain and curtailment of electric power supplies. The Government of Nigeria has increased the scales of royalties on both columbite and tin. It has been asserted that these scales are not justified by existing working costs and that this situation has made the lower grade ore uneconomical.[12]

Reserves of columbite in Nigeria, as of March 31, 1951, were estimated at about 10,000 long tons, of which about 7,000 tons was proved.[13]

South-West Africa.—This country reported a production of 3,794 pounds of columbite-tantalite during 1951, principally from the Karabib-Usakos area.

Uganda.—Columbite production came from the Ankole-Kigezi area; largest producer was the African Base Metals Concern, with workings in the Kakanena-Kavu, Savami, and Ankole districts. The known columbite-tantalite area extends from Dwata to Kabira, in northwest Kashara County, and south to Kamezi on the Ruanda border.[14] Columbite has been reported in northern Kinkizi.[15] A

sample of pyrochlore from Sukulu Hill, Tororo, Uganda, was submitted by the Geological Survey of Uganda to the United States Bureau of Mines for beneficiation tests. Flotation tests were not successful, although not enough tests were made to be conclusive.

GALLIUM [16]

Gallium is unique among metals in that it remains liquid through a temperature range of 3,515° F.—from a melting point of 85.5° F. to a boiling point of 3,601° F. Unfortunately, it is extremely corrosive and consequently difficult to handle, particularly at higher temperatures. Although gallium is as abundant as lead in the crust of the earth, the price that it commands is over twice that of gold. Few significant commercial concentrations of the metal have been found. The richest known gallium-bearing mineral, germanite, contains up to 1.85 percent of the metal. The ores of tin, zinc, and aluminum contain varying small amounts of gallium. Some Bolivian tin ores run as high as 0.05 percent gallium, and aluminum ores have been found to contain 0.002 to 0.008 percent gallium. Flue dust from certain coals of east-central England have assayed up to 0.17 percent gallium.

Production.—Gallium metal was produced in 1951 by the Aluminum Ore Co., East St. Louis, Ill.; and the Anaconda Copper Mining Co., Great Falls, Mont.

Consumption and Uses.—Demand for gallium in 1951 was negligible. No new applications were developed. The principal use of the metal, as in recent years, was as a component in the construction of direct-reading fused quartz thermometers. Minor amounts of gallium were used in optical mirror backings, dental alloys, gallium-vapor lamps, and as an excitant in phosphors for fluorescent lighting and luminous paints. Research studies were conducted on gallium and alloys of the metal with tin, aluminum, and zinc for potential use as a liquid-metal heat-transfer medium in nuclear energy apparatus.[17]

Prices.—Quotations on gallium metal, 99.9 percent pure, in 1951 continued the same as in 1950, with the metal offered at $4.50 per gram in lots of less than 100 grams; $3.50, for 100 to 999 grams; and $3.00, for 1,000 to 2,499 grams.

GERMANIUM [18]

Through development of improved germanium diodes and transistors, further and substantial progress was achieved in 1951 toward the imminent revolution in electronics, which has, according to the prognosticators, far-reaching implications.

Production.—Germanium production, principally in the form of the dioxide, increased about 80 percent in 1951 compared with 1950 and reached an all-time high. The Eagle-Picher Co., Joplin, Mo., maintained its position as the leading domestic producer of germanium and its compounds. A relatively small but significant output of germanium dioxide was reported by the American Steel & Wire Co.

(subsidiary of the U. S. Steel Corp.), Donora, Pa., the only other producer. American Zinc, Lead & Smelting Co. announced that a new unit for the recovery of germanium was under construction at its Fairmont City, Ill., plant and would be placed in operation during 1952.[19] Toward the close of 1951 the Eagle-Picher Co. filed a tax-amortization application with Defense Materials Procurement Agency in connection with its plans to increase the capacity of its germanium-production facilities at Joplin, Mo. Action on the application had not been completed at the year end.

Consumption and Uses.—Apparent consumption of germanium and its compounds in 1951, based on producers' shipments and imports, increased slightly more than 100 percent compared with 1950 and was almost identical in quantity with domestic production in 1951. As in the last several years, virtually all the germanium consumed was used in the metal form by the electronics industry for the production of diodes and transistors. (*See* Germanium review in the Minor Metals chapter, Minerals Yearbook 1950.) About 6,000,000 diodes were said to have been made in 1951 and were extensively used in television receivers.[20] Principal manufacturers of diodes and transistors in 1951 included General Electric Co., Syracuse, N. Y.; Philco Corp., Philadelphia, Pa.; Raytheon Manufacturing Co., Newton, Mass.; Sylvania Electric Products, Inc., Woburn, Mass.; and Western Electric Co., Allentown, Pa. Numerous companies, most of them already in the general electronics field, were reportedly preparing to produce diodes and transistors in 1952.

Transistors are of two types, the contact type and the junction type. The contact type was developed first, and a large part of the improved performance of the transistor results from development of the junction type. A germanium crystal touched by two closely spaced fine wires comprised the contact transistor, whereas in the junction transistor this point-contact arrangement has been replaced by a large-area contact. A thin layer of electrically positive (electron-deficient) germanium is sandwiched between two electrically negative (electron-rich) germanium ends. Transistor action takes place over the entire area of contact (junction) between the two types of germanium. The junction transistor therefore operates more efficiently and consumes far less power than the contact transistor.[21]

Stocks and Prices.—Producers' 1951 year-end stocks of germanium were larger than at the close of 1950 but were relatively low owing to the strong demand for the metal that prevailed during 1951. Germanium was quoted by E&MJ Metal and Mineral Markets at $180 per pound throughout 1951.

Foreign Trade.—Imports of germanium in 1951 comprised 319 pounds of germanium dioxide, valued at $66,121, from Germany and the United Kingdom.[22] Data on United States exports of germanium are not available.

Technology.—An investigation of the physical metallurgy of germanium was begun in the latter part of 1951 by the Bureau of Mines at its Mississippi Valley Experiment Station, Rolla, Mo.

The investigation involved the design and construction of special furnaces for reducing germanium oxide and for remelting and casting the metal and development of new instruments for measuring the various electrical properties of germanium.

A metallurgical process was described for recovering germanium from flue dusts produced in burning British coals. Recovery in the regulus of more than 90 percent of the germanium in the dust was achieved, followed by extraction of 90 to 95 percent of the metal in the regulus.[23] Direct reduction of germanium tetrachloride with zinc vapor to produce germanium metal of electronic grade was discussed. The purity and electronic properties of the germanium equaled or exceeded those of germanium prepared by the standard hydrolysis and hydrogen reduction of germanium dioxide.[24]

In an investigation of junction transistors, the effects of diffusion of electrons through a thin p-type layer of germanium was studied in specimens consisting of two n-type regions with the p-type region interposed.[25] Research investigations were conducted on various physical and electrical characteristics of germanium semiconductors.[26] The electrical resistivity of aluminum alloys containing germanium was found to increase linearly with the atomic percentage of the solute atoms.[27]

INDIUM[28]

Indium is a silver-white metal with a bluish tinge and is ductile, malleable, softer than lead, crystalline, and diamagnetic. The metal is widely distributed in the crust of the earth but generally found only as traces with the ores of zinc, lead, tin, tungsten, and iron. Commercial production of indium has been principally from zinc-smelter residues, which have been found to contain up to 1.0 percent of the metal.

Production.—The indium content of metal and compounds produced domestically in 1951 exceeded by about 10 percent the previous all-time high production of 1950. Principal producers of indium were the American Smelting & Refining Co., Denver, Colo., and Perth Amboy, N. J.; the Anaconda Copper Mining Co., Great Falls, Mont.; and the Cerro de Pasco Copper Corp., Brooklyn, N. Y.

Uses.—The chief use of indium has been as a plating for engine bearings, especially where high bearing loads, elevated operating temperatures, and severe conditions of lubricant corrosion are encountered. A small percentage of indium added to silver-lead solders materially improves the coverage, spreadability, and bonding strength of such solders.

World Review.—Indium production in Peru was reported to be 80,853 grams, which was appreciably less than the 1950 production of 514,000 grams. Canada, which produced 154,000 grams in 1950, had an estimated production of 30,000 grams of indium for 1951.

RARE-EARTH MINERALS AND METALS [29]

Nature has been relatively generous in distributing rare-earth elements throughout the world and has endowed this country with two commercial sources—monazite, a rare-earth phosphate containing thorium, and bastnaesite, a rare-earth fluocarbonate. The known properties of the individual members of the rare-earth group are characteristically similar; ordinarily the elements occur together in the same minerals and are difficult to separate. The group as a whole is as abundant in the earth's crust as cobalt, boron, zinc, or lead.

Interest in domestic deposits of monazite and bastnaesite continued to increase during 1951. The Bureau of Mines, under contract to the Atomic Energy Commission, continued to examine stream gravels in Idaho, Montana, Wyoming, North Carolina, and South Carolina as part of a program to evaluate the monazite deposits of the United States; the Geological Survey collaborated with the Bureau in examining several southeastern deposits. The bastnaesite deposit near Mountain Pass, San Bernardino County, Calif., was mapped by the Geological Survey. An examination, incidental to the mapping, showed that the deposit covers an area roughly 6 miles long and 2 miles wide, southeast of the Birthday claims originally discovered in 1949. The bastnaesite occurs in veins and bodies of barite-carbonate rock associated with shonkinite and syenite.

Reserves of rare-earth minerals, especially those in Idaho and California, point to the possibility of this country becoming self-sufficient, with respect to these source materials, within the not too distant future.

Production.—Domestic monazite production for 1951 was twice the output for 1950. Operations in the monazite-rich gravels of Idaho accounted for the increase. Significant production also came from Florida. The producing companies were Baumhoff-Marshall Co., Boise, Idaho; Warren Dredging Corp., Boise, Idaho; Humphreys Gold Corp., Jacksonville, Fla.; and Climax Molybdenum Co., Leadville, Colo.

Monazite-production statistics are classified because the mineral comes under the regulations of the Atomic Energy Act of 1946, being a source of thorium, a fissionable material. No bastnaesite production was reported during the year.

Digitized by Google

Consumption and Uses.—Principal monazite processors are Lindsay Light & Chemical Co., West Chicago, Ill.; Rare Earths, Inc., Paterson, N. J.; and Maywood Chemical Works, Maywood, N. J. Producers of mischmetal and ferrocerium include: Cerium Metals Corp., New York, N. Y.; General Cerium Corp., Edgewater, N. J.; New Process Metals Corp., Newark, N. J.; and Kent Metal & Chemical Co., Edgewater, N. J.

Large quantities of rare-earth fluorides and oxides are used as cores for high-luminosity carbon electrodes. Ordinary carbon arc lamps, although of high intensity, dissipate much of this intensity in the infra-red region of the spectrum. Addition of the rare-earth compounds results in a brilliant white light because of the intense emission in the visible region. High-speed photography has been made possible by the use of these high-luminosity electrodes. The pyrophoric property of ferrocerium, an alloy of iron and the rare-earth metals, makes the material desirable for striking flints used in mechanical lighters. This property has made possible tracer bullets and luminescent shells.

Mischmetal, the mixture of all of the rare-earth elements in metallic form, contains 45 to 55 percent cerium. An aluminum alloy with 11 percent mischmetal has stress-rupture properties superior to present commercial alloys in the range of 700° to 800° F.[30] The creep resistance of extruded magnesium is improved in the range of 400° to 600° F. Additions of rare-earth metals improve the hot-workability of austenitic chromium-nickel and other high-alloyed steels.[31]

Prices.—During 1951 quotations for mischmetal and ferrocerium remained unchanged at $4.50 and $8.00 per pound, respectively. High-purity cerium metal was offered at $18.00 per pound.

Foreign Trade.—Receipts of mischmetal and ferrocerium alloys for 1951 totaled 699 pounds valued at $4,543. Germany was the principal source. Imports of rare-earth chlorides from Brazil amounted to 822,125 pounds, valued at $281,681. (*See* the Minor Metals chapter, Minerals Yearbook, 1950, p. 1325, for statistics covering imports of mischmetal and ferrocerium, 1924–50; cerium and other rare-earth compounds, 1922–50; and exports of mischmetal and ferrocerium, 1942–50.)

WORLD REVIEW

India.—Except for a small tonnage shipped to England, India has had a complete embargo on monazite exports since 1947. The Indian Government has interest in controlling the exports of monazite because of the thorium content. According to a report published in 1951, Indian Rare Earths, Ltd., was being set up at Alwaye, in Travancore, by the Government of India and Travancore to operate a plant to process 1,500 tons of monazite annually. Societe de Produits Chimiques des Terres Rares, of France, was making the plant installation and contributing technical assistance until Indian personnel could be trained.[32]

Digitized by Google

Brazil.—Brazil, like other governments, has placed tight restrictions on the export of monazite. Deposits of monazite in the vicinity of Victoria, State of Espirito Santo, were being worked by the Monazita e Ilmenita do Brasil and Foote Minerios Industrializados. The latter company lost an attempt to block by injunction the Government ruling that prohibits export of the mineral to the United States.[33] A new plant for treating monazite has been erected at Guarapari, Espirito Santo.[34]

RHENIUM [35]

Rhenium, first discovered in Germany in 1925, has been one of the neglected elements, but recent research at the University of Tennessee suggests that it may have important specialized uses. It is a heavy, silver-white metal with a melting point of 3,440° C. abs. This metal alloys readily with tungsten, nickel, cobalt, tantalum, platinum, rhodium, iridium, gold, and iron. Rhenium is widely distributed in the crust of the earth but is not found in any commercial concentrations. Molybdenite has proved to be the richest mineral source of the element. The rhenium content of domestic molybdenites was reported to run as high as 0.05 percent, although specimens of this mineral from Norway have assayed up to 0.30 percent. Flue dust from roasting molybdenum concentrates is the principal commercial source of the metal.

Production and Prices.—Rhenium and potassium perrhenate have been produced by the Chemistry Department of the University of Tennessee since 1942. Only a few pounds of the metal has been produced yearly. The price varied with the quantity purchased. In pound lots the price was reported to be $900.00 per pound.

Uses.—The high melting point gives rhenium value in high-temperature alloys, which offer excellent corrosion-resistant properties. The metal has a longer life than tungsten when operated at any given temperature. Thermocouples of platinum-rhenium and platinum, of platinum-rhenium and rhodium, or iridium-rhenium and iridium have high electromotive forces and can be used at temperatures up to 1,900° C.

SELENIUM AND TELLURIUM [36]

Selenium and tellurium are closely associated mineralogically and have many properties in common. Moreover, they are both derived from the same principal industrial source—blister copper. Economically, however, the two metals differed markedly in 1951. Selenium was a strategic metal in limited supply, the year-end stocks of which were at the lowest level since 1935. Tellurium, on the other hand, was abundant, and at the close of the year overall stocks, including the metal content of producers' stocks of compounds and unprocessed anode slimes, exceeded a 5-year supply of the metal on the basis of apparent consumption in 1951.

Production.—Domestic output of elemental selenium in 1951 was 457,004 pounds compared with 511,325 pounds in 1950—a decline of

[33] Engineering and Mining Journal, vol. 152, No. 7, July 1951, p. 208.

Digitized by Google

about 11 percent, attributable largely to (1) reduced production of high-selenium copper at one mine, (2) the accumulation of selenium-containing anode slime during the year at one copper refinery, and (3) a decrease of about 4 percent in the production of electrolytic copper in the United States. Domestic production of elemental tellurium in 1951 totaled 160,933 pounds compared with 59,713 pounds in 1950.

TABLE 6.—Salient statistics of elemental selenium and tellurium in the United States, 1942–46 (average) and 1947–51, in pounds

Year	Selenium					Tellurium		
	Production	Producers' shipments	Producers' stocks at end of year	Imports [1]		Production	Producers' shipments	Producers' stocks at end of year
				Pounds	Value			
1942–46 (average)	475,408	454,394	388,637	191,172	$328,351	86,769	61,046	156,101
1947	512,648	489,415	280,368	529,175	893,171	45,248	71,300	122,717
1948	561,156	570,718	270,806	267,118	489,762	48,806	78,788	92,735
1949	468,502	317,960	334,067	171,581	317,145	109,021	64,278	135,605

1951	457,004	455,608	85,947	246,552	1,017,863	160,933	144,972	113,210

[1] Includes selenium salts.

Producers of selenium and tellurium and their compounds in 1951 were the American Smelting & Refining Co., Baltimore, Md.; International Smelting & Refining Co., Perth Amboy, N. J.; and United States Metals Refining Co., Carteret, N. J. The United States Smelting, Refining & Mining Co. produced tellurium and tellurium compounds at its East Chicago, Ind., lead refinery. Kennecott Copper Corp. proceeded with the installation of facilities at its Garfield, Utah, copper refinery for the recovery of selenium and tellurium, with initial recovery operations scheduled for September 1952.

Consumption and Uses.—Apparent consumption (producers' domestic shipments plus imports) of elemental selenium and elemental tellurium in 1951 was 702,130 and 144,972 pounds, respectively, representing a 35-percent decline for selenium and a 48-percent increase for tellurium, compared with the respective apparent consumption in 1950. In the instance of selenium, the lower apparent consumption in 1951 reflected reduced production and a decline in imports rather than any decrease in demand. On the contrary, the metal was in such short supply that on December 10, 1951, the National Production Authority issued Order M–91 placing both imported and domestically produced selenium under complete allocation. NPA announced that the action was necessary if essential defense requirements for selenium were to be met.

The principal uses of selenium in 1951 were (1) in manufacturing rectifiers used to convert alternating current to direct current in television and radio sets and to perform the same function as power tubes; (2) in producing special grades of stainless steel to improve machinability and in casting stainless steel to provide gas control and thereby assure soundness of castings; (3) as a decolorizer in the glass industry; and (4) for diversified chemical purposes, including its use (a) in the production of pigments and enamels, (b) as a rubber accelerator, and

Digitized by Google

(c) as a catalyst in the synthesis of organic chemical and drug products. High-purity-grade (99.99 plus percent) and DDQ-grade (99.95 percent) selenium are used for manufacturing rectifiers. In the glass and pigment industries, commercial-grade (99.5 percent) selenium is used. Selenium dioxide is employed as a catalyst in the preparation of chemicals and drugs. Ferroselenium is used in producing stainless steel.

Tellurium was used principally (1) in manufacturing alloys, such as tellurium lead, tellurium copper, and various tellurium bronzes, and (2) in the rubber industry as a secondary vulcanizing agent. Minor uses were as an additive and core wash to induce chill in the manufacture of iron castings, and as a coloring agent in the production of art glass and ceramics. A tellurium copper with a machinability approaching that of free-cutting brass and with an electrical conductivity of 90 percent of that of pure copper was produced. A tellurium bronze also became available that had high strength, hardenability, ease of machining, and corrosion resistance. Tellurium imparts hardness, toughness, and increased corrosion resistance to lead. In rubber, tellurium provides resistance to heat and aging.

Stocks.—Producers' stocks of elemental selenium decreased 31 percent in 1951, whereas those of elemental tellurium increased 16 percent. The stocks of selenium at the end of 1951 represented less than a 2-month supply, based on apparent consumption for the year.

Prices.—Selenium, black, powdered, 99.5 percent pure, was quoted at $3.00–$3.50 per pound throughout 1951. The quotation for tellurium continued unchanged at $1.75 per pound, as in the preceding 12 years.

Foreign Trade.—Imports of selenium and its salts in 1951 totaled 246,552 pounds, valued at $1,017,863, a decrease of 32 percent in quantity but an increase of 33 percent in value, compared with 1950. Canada was the source of 200,622 pounds (81 percent) of 1951 imports, valued at $756,744. Japan furnished 20,793 pounds, valued at $145,165, and 19,815 pounds, valued at $97,719, was received from Sweden. Germany, Mexico, and Belgium supplied most of the remainder. Tellurium imports were virtually nil, amounting to 25 pounds of tellurium in compounds received from Canada. Data on exports of selenium and tellurium are not available.

World Review.—Canadian production of selenium increased 45 percent in 1951 in response to strong demand for defense purposes. The total selenium output was 382,603 pounds valued at C$1,239,633, compared with 261,973 pounds valued at C$633,975 in 1950. Tellurium production decreased from 10,075 pounds valued at C$19,143 in 1950, to 8,913 pounds valued at C$16,400 in 1951.[37]

About three-fourths of the total selenium production in Canada in 1951 was recovered by Canadian Copper Refiners, Ltd., at its Montreal East, Quebec, refinery from copper anodes produced from the copper-gold ores of Noranda Mines, Ltd., Noranda, Quebec, and from blister copper derived from the copper-zinc ores of Hudson Bay Mining & Smelting Co., Ltd., Flin Flon, Manitoba. About one-fourth of the total production was recovered at the Copper Cliff, Ontario, refinery of the International Nickel Co. of Canada, Ltd., from the Sudbury

[37] Dominion Bureau of Statistics, Ottawa, Ontario, Canada.

Digitized by Google

copper-nickel ores. Selenium and its compounds were also produced by the International Nickel Co. of Canada, Ltd., at its Clydach refinery, near Swansea, Wales, United Kingdom.

THALLIUM [38]

Thallium is recovered commercially from flue dust and residues accumulated in certain plants and smelters that produce lead, zinc, copper, cadmium, sulfuric acid, and white arsenic.

Production.—The Globe cadmium refinery of the American Smelting & Refining Co., at Denver, Colo., was the sole producer of thallium metal in the United States. Domestic output of thallium metal and sulfate totaled about a few thousand pounds during 1951.

Consumption and Uses.—Producers' shipments of thallium metal and sulfate in 1951 indicated that thallium was consumed at the same rate as in the previous year. The use of thallium compounds for rodent and insect control declined whereas use of thallium in scintillator counter crystals and as a phosphor activator increased.

Thallium-bromide-iodide synthetic optical crystals were used as prisms and windows for use in infrared spectroscopy and infrared achromatic lenses, and as lens components for microscope objectives for use in infrared optical instruments.

Prices.—Trade journals quoted thallium metal and sulfate in 1951 at $12.50 and $10.50 per pound, respectively, in 10-pound lots.

Technology.—Thallium was reported to be more effective than lead in improving gasoline performance, according to the findings incorporated in United States Patent 2,562,885.[39]

The Salt Lake Experiment Station of the Bureau of Mines, at Salt Lake City, Utah, investigated methods for recovering thallium from certain products of American Smelting & Refining Co. smelters.

GREENSAND [2]

THE FOLLOWING firms reported production of greensand during 1951: The Permutit Co., 330 West 42d St., New York, N. Y.; Zeolite Chemical Co., Medford, N. J.; and Inversand Co., Clayton, N. J. All production was from open-pit operations in Burlington and Gloucester Counties, N. J., and all shipments were for water softening and purification.

Prices of refined greensand ranged from about $54–$122 per short ton, f. o. b. shipping point.

TABLE 1.—Greensand marl sold or used by producers in the United States, 1946–51

Year	Short tons	Value	Year	Short tons	Value
1946	5,140	$424,900	1949	6,128	$276,564
1947	8,337	432,980	1950	3,935	304,321
1948	7,269	392,959	1951	5,067	263,944

JEWEL BEARINGS [3]

Jewel bearings manufactured from synthetic corundum have largely replaced natural mineral bearings used in watches and precision instruments. Jewel bearings made from synthetic spinel and glass also are used in small quantities. Compared with natural stones, synthetic corundum stones (ruby and sapphire) are of greater purity, usually flawless, and less expensive. Synthetic sapphires are produced from chemically pure, finely ground alumina (Al_2O_3). Small quantities of chromium oxide are added as a pigmentary material in the production of rubies. The aluminum oxide passes through a hydrogen-oxygen flame, and the molten oxide forms into a single bullet-shaped crystal or boule. The boule is removed from the furnace and is split longitudinally, sawed into blanks, ground into rondelles, drilled, cut to various shapes, polished, and glazed into a marketable jewel bearing.

The Swiss jewel-bearing industry, controlled by three separate unions and the Swiss Export Association, dominates world production. Most of the United States supply of jewel bearings is imported from Switzerland.

Jewel bearings are in group I on the Munitions Board's List of Critical and Strategic materials. Three different classifications have been stockpiled, but there were no new purchases for the National Stockpile in 1951.

TABLE 2.—Salient statistics of the jewel bearing industry in the United States, 1948–51

Production.—Domestic production of jewel bearings in 1951 was less than 12 percent of the total consumption (tables 2 and 3). A total of 1,201,000 blanks and 9,877,000 finished jewels was produced in 1951, approximately 51- and 197-percent increases above the 1950 output. Essentially, no watch jewels are made in the United States, except for a small quantity of pallet stones. The only jewel bearings manufactured domestically in any appreciable quantities are cup jewels. The production of V-jewels, endstones, and ring-hole jewels is small. Jewel bearings are manufactured in several plants at Waltham, Mass.; Trenton and Perth Amboy, N. J.; and Lancaster, Pa.

Consumption.—Industry consumed 85,030,000 finished jewels during 1951, an increase of 20 percent compared with 1950. Jewel bearings are used where it is necessary to minimize the friction of moving small parts. The bearings find universal application in watches, gages, meters, indicators, fine scales and balances, time fuses, and other instrumentation. Synthetic sapphire is preferred for industrial bearings and synthetic ruby for watch jewels. The most common varieties of watch bearings are cap jewels, pallet stones, hole jewels, and roller pins. Standard types of industrial bearings are cup, vee, ring, and cap.

Stocks.—At the close of 1951, company stocks totaled 2,619,000 blanks, 710,000 semifabricated jewels, and 97,390,000 finished jewels. Although semifabricated jewels in stock increased 34 percent, both stocks of blanks and finished jewels decreased.

KYANITE, ANDALUSITE, SILLIMANITE AND DUMORTIERITE [4]

Production.—Only two companies produced kyanite in the United States in 1951, namely, Commercialores, Inc., 39 Cortlandt Street, New York, N. Y., (from deposits near Clover, S. C.), and Kyanite Mining Corp., Cullen, Va. (from a property near Farmville, Prince Edward County, Va.). Both companies reported increases in production in 1951 compared to 1950. The Bureau of Mines is not at liberty to publish figures on domestic production.

No production of andalusite and dumortierite was reported to the Bureau of Mines for 1951.

Consumption and Stocks.—Consumption of imported kyanite in 1951 was 16,508 short tons compared with 15,874 in 1950. Stocks at the end of 1951 were 1,891 short tons compared with 4,772 short tons in 1950.

Prices.—As reported by E&MJ Metal and Mineral Markets for December 1951, quotations on kyanite were as follows: Per short ton f. o. b. point of shipment, Virginia and Soutb Carolina, 35-mesh, carlots, in bulk, $29; in bags, $32; for 200-mesh, carlots, in bags, $40. Quotations on imported kyanite (57-to 59-percent grade), in bags, were $60 to $65 per short ton, c. i. f. Atlantic ports.

Foreign Trade.—Imports and exports of kyanite and allied minerals for 1951 are shown in table 4. India furnished 53 percent and British East Africa 41 percent of the total United States imports. India furnished about the same tonnage, whereas British East Africa furnished 32 percent more than in 1950.

[2] Less than 0.5 ton.

Synthetic Mullite.—Before World War II most of the kyanite-mullite refractories were made using imported Indian kyanite as the main constituent. However, since the end of the war changing political and economic conditions and the uncertainty of obtaining high-grade material have increased the demand for natural high-grade domestic aluminum silicate minerals or synthetic mullite except electrocast refractories. Although natural aluminum silicates are found in the Southeastern States, the intermountain area, the Southwest, and in the Pacific Coast States, most of the deposits are undeveloped, of low grade, inaccessible, or disadvantageously located with respect to consuming areas. Only 2 properties, 1 in Virginia and 1 in South Carolina, operated in 1951. Neither deposit contains material comparable to massive Indian kyanite.

The meager prospecting and exploration through 1951 indicated the improbability of locating adequate domestic sources of massive mullite-forming minerals. Concentrates obtained from disseminated ores can be used directly to produce many types of refractories, including high-temperature cements, and after pelletization can replace massive kyanite for some uses.

The development of synthetic mullite appeared to offer the best means for future fulfillment of needs being served by imported massive kyanite. The cost of mullite grain produced by sintering low-iron siliceous bauxite is comparable to mullite produced from first quality, imported kyanite. Mullite grain produced by the fusion process is of much higher quality than that produced by sintering and is used in certain applications even though it is much higher in price than any other mullite grain.

Digitized by Google

The Bureau of Mines Electrotechnical Laboratory at Norris, Tenn., continued to check kyanite and mullite materials offered for National stockpile purchasing and evaluated similar materials from private industry to determine their acceptability as substitutes for imported kyanite.

LITHIUM [5]

At present the four most important sources of lithium are the minerals spodumene, lepidolite, and amblygonite, which are recovered only from pegmatites, and the compound dilithium-sodium phosphate recovered from brine. Petalite is used in small quantities in certain ceramics. Zinnwaldite and triphylite-lithiophilite have been utilized but are limited in quantity available and low in lithium content.

The structure of pegmatites and its relation to exploration, development, and mining were discussed.[6]

During World War II military requirements pushed domestic production of lithium minerals and compounds to record levels. When Government contracts were canceled at the end of 1944, many producers were left with excess capacity, and at that time other markets of comparable size were not available. A few mines were put in standby condition, and others were abandoned. During the next few years the remaining producers intensified their research and market development programs. As a result, important new uses were developed, and the market for lithium minerals and compounds in such applications as glass, ceramics, and lubricants had greatly increased by the end of 1951. The lithium industry had expanded rapidly, and further expansions were underway.

TABLE 5.—Shipments of lithium ores and compounds from mines in the United States, 1935–39 (average) and 1947–51

Year	Ore (short tons)	Value	Li_2O (short tons)	Year	Ore (short tons)	Value	Li_2O (short tons)
1935–39 (average)...	1,327	$48,280	88	1949.....	4,838	$345,970	475
1947.....	2,441	151,113	199	1950.....	9,306	579,922	747
1948.....	3,881	210,792	291	1951.....	12,897	[1] 896,000	956

[1] Partly estimated.

The properties of lithium minerals and their occurrence, production, and relation to research on thermonuclear reactions were described in an article.[7]

Production.—A number of firms reported production of lithium ores and compounds in 1951: American Potash & Chemical Corp., 3030 West 6th St., Los Angeles 54, Calif., recovered dilithium-sodium phosphate from the brine of Searles Lake, Calif. This material was processed in its plant at Trona on the edge of the lake. The raw brine contained only a trace of lithium, which was precipitated in the main plant cycle as dilithium-sodium phosphate and recovered by flotation.

[7] De Ment, Jack, Hunting Lithium for Hydrogen Bomb: Mineralogist, vol. 19, No. 9, September 1951, pp. 379–385, 402, 404, 406, 408.

Digitized by Google

In the fall of 1951, Foote Mineral Co., 18 West Chelten Ave., Philadelphia 44, Pa., began production of spodumene from extensive deposits in the vicinity of Kings Mountain, N. C. Most of this material was processed into lithium compounds at the firm's plant at Exton, Pa. Some was sold in mineral form, principally for use in ceramics.

Lithium Corp. of America, Rand Tower, Minneapolis, Minn., produced spodumene from the Edison mine in the Black Hills of South Dakota. The material was concentrated by the sink-float method and shipped to the firm's subsidiary, Metalloy Corp., near Minneapolis, for conversion to lithium compounds and metal.

Maywood Chemical Works, Maywood, N. J., recovered spodumene from the Etta mine in Pennington County, S. Dak. This operation was both underground and open pit, and the spodumene was hand-picked from the mined ore. Spodumene was converted to lithium compounds and metal at Maywood, N. J.

Black Hills Keystone Corp., produced spodumene and small quantities of amblygonite from the Ingersoll mine near Keystone, S. Dak. George C. Bland reported production of spodumene from the Beecher Lode in Custer County, S. Dak. John Fisher produced a small tonnage of amblygonite from the Dike Lode in Keystone County, S. Dak. Shipments of spodumene by Earl Anderson were reported from Castle Hot Springs, Ariz.

Technology.—Experiments in refining lithium metal were described. Commercial lithium metal containing about 0.5 percent sodium was vaporized at low pressure and condensed to yield a metal containing as low as 0.001 percent sodium. Operating data were given and equipment was described.[8]

Prices.—Trade-journal quotations in 1951 of prices for lithium ores were as follows: Amblygonite, air-floated, carlots, $110 per ton; lepidolite, 4 percent Li_2O, powdered, carlots, $80 per ton; spodumene, per short ton unit of lithium oxide contained, $6–$8 on 6-percent grade. These prices were all nominal.

American Potash & Chemical Corp. continued to offer dilithium-sodium phosphate at about $9 per unit of Li_2O.

Mozambique.—The Empresa Miniera do Alto Ligonha, S. A. R. L., leading beryl producer in Mozambique, reported the recovery of an appreciable amount of lepidolite in the hand-mining and sorting operations that produce the beryl, and the company stated that this lepidolite output could amount to over 250 tons monthly. An average analysis of the lepidolite was reported by the company to be as follows:[9]

	Percent
Li_2O	4.8
Al_2O_3	14.2
SiO_2	40.6
$Na_2O \cdot K_2O$	39.6
Total	99.2

Belgian Congo.—Spodumene was a newcomer to the tabulated mineral exports from Belgian Congo. The statistics of production are not available, but this mineral occurs as an important constituent of the Manono and Kitotolo pegmatites where Geomines is mining tin, and the first exports, totaling 5,200 metric tons valued at fr.8,034, were made in the first quarter of 1951. Reportedly these exports went to Belgium.[10]

MEERSCHAUM [11]

Meerschaum, or the mineral sepiolite, is a soft, fine-grained, earthy material used principally for making pipes and other smokers' articles. There has been a small, sporadic production in the United States, but virtually all the world supply for many years has come from Turkey. Imports from that source have increased steadily since 1947.

TABLE 7.—Meerschaum imported for consumption in the United States, 1946–51 [1]

[U. S. Department of Commerce]

Year	Pounds	Value	Year	Pounds	Value
1946	14,469	$21,785	1949	5,844	$13,897
1947	5,758	10,534	1950	9,621	18,549
1948	3,000	10,070	1951	11,289	13,384

[1] 1946–49 and 1951, all from Turkey; 1950: Italy: 20 pounds, $120; Turkey: 9,601 pounds, $18,429.

MINERAL-EARTH PIGMENTS [12]

Production.—Demand for mineral-earth pigments declined slightly in 1951, and sales of most products were lower than in 1950. Sales of mineral-earth pigments totaled 126,000 short tons valued at $14,987,000, approximately 2.2 percent less than that reported in 1950, as shown in table 8. Natural mineral-earth pigments accounted for 65 percent of the total tonnage sold in 1951. Red oxides represented 50 percent of the natural pigments sales, and yellow oxides represented 10.2 percent. Sales of synthetic pigments totaled 44,769 short tons or 35 percent of the total sales of mineral-earth pigments. Pure red oxides (98 percent or better Fe_2O_3) represented 48 percent of the synthetic sales, and pure yellow oxides (85 percent or better Fe_2O_3) 31 percent.

During the year, a survey was begun to study supply and demand and other problems of the pigment industry. Mineral-earth pigments was one of the groups included in this study.[13]

Total	129,256	14,762,782	126,432	14,987,075

Prices.—According to the Oil, Paint, and Drug Reporter, prices were quoted as follows during December 1951 (in cents per pound, bags, works, carlots, unless otherwise noted):

Mineral black, 1.6–6.75.
Metallic oxide, brown, 3.75.
Sap brown, crystals, 12.
Sap brown, powdered, 13.
Sienna, burnt, 4.25–15.25.
Sienna, raw, 4.5–13.
Umber, burnt, American (bbl.), 6.
Umber, Turkey type, 6.25.
Vandyke, brown, (bbl.), 11.
Metallic red (bbl.), 2.5.
Natural red iron oxide, 5.75–9.25.
Persian Gulf oxide, 6.75–7.
Spanish oxide (bbl.), ex dock, 5.75.
Natural yellow iron oxide, 1.41–2.50.
Natural yellow iron oxide, French type, 4.5.
Natural yellow iron oxide, Peruvian type, 1.85–2.10.
Golden American yellow ocher, 1.25–2.75.
Synthetic black iron oxide, 11.75.
Synthetic brown iron oxide (l. c. l.), 13.
Synthetic red iron oxide, 12.25–12.50.
Special, high color, red iron oxide, 6.
Venetian reds, 3.50–5.25.
Synthetic yellow iron oxide, 10.

Foreign Trade.—Imports of mineral-earth pigments in 1951 totaled 14,000 short tons valued at $1,008,000, an increase of 53 percent in quantity and 72 percent in value compared with 1950, as shown in table 9. Synthetic iron-oxide pigments represented 38 percent of the total imports, natural iron-oxides 25 percent, and umbers, crude and refined, 25 percent.

Exports of ocher, sienna, umber, and other iron-oxide pigments, principally to Canada, totaled 4,652 short tons valued at $738,000—a decrease of 16 percent in quantity and an increase of 4 percent in value from the 1950 figures. Data for 1948–51 are shown in table 10.

MINERAL WOOL [14]

The total value of mineral wool produced in the United States during 1951 from rock, slag, and glass was $134,128,000, compared with $115,664,000 (revised figure) in 1950 and $93,023,000 in 1949, according to the Bureau of the Census. Latest use statistics available are for 1947 and were published on page 1362 of Minerals Yearbook 1948. The average number of persons employed by the mineral-wool industry during 1951 was 10,374 compared with 9,244 in 1950 and 7,544 in 1949. Of the number reported in 1951, 8,583 were production workers.

Exports of mineral-wool products from the United States during 1951 were valued at $1,511,486 compared with $1,132,454 in 1950.

Experiments showed the value of old slag piles as a source of raw material for mineral-wool manufacture.[15]

Materials for mineral-wool manufacture was the subject of a recent investigation by the Bureau of Mines.[16] Insulation of pellet-type rock-wool insulation [17] and use of mineral-wool insulation on steam turbines and boilers were described in technical magazines.[18]

OLIVINE [19]

In 1951 sales of olivine increased 115 percent in tonnage and 127 percent in value over 1950.

The same firms reported production in 1951 as reported in 1950: Harbison-Walker Refractories Co., Farmers Bank Building, Pittsburgh, Pa., from its Addie quarry near Addie, N. C.; The United Feldspar & Minerals Corp., Spruce Pine, N. C., from its Wray mine near Green Mountain, N. C.; and The H. P. Scheel Co. from its Big Slide mine, near Sedro-Woolley, Wash. Olivine is used in production of refractory brick, shapes, and high-temperature cements.

TABLE 11.—Olivine sold or used by producers in the United States, 1946–51

Year	Short tons	Value	Year	Short tons	Value
1946	7,649	$92,868	1949	3,528	$56,850
1947	10,838	129,094	1950 [1]	4,103	59,402
1948	4,766	86,230	1951	8,816	134,892

[1] Revised figures.

PERLITE [20]

Production of expanded perlite, a material virtually unknown on a commercial basis before World War II, was 33 times greater in 1951 than in 1946. Total output of expanded perlite in 1951 reached

134,000 short tons, and the quantity of expanded perlite sold or used was 133,000 short tons valued at $7,243,000. The quantity of crude rock sold or used by producers was 182,000 short tons valued at $810,000. The difference between the quantity of crude sold or used at own plant and the quantity of expanded material sold was accounted for by losses in transit, unexpandable material in the furnace feed, unsalable fines produced, stocks in transit or in storage, and the loss of moisture weight during furnacing.

In 1951 active mines were located in 7 Western States, with deposits in Nevada, New Mexico, and Colorado furnishing 88 percent of the total requirements of crude rock.

TABLE 12.—Crude and expanded perlite produced and sold or used by producers in the United States, 1947–51

Year	Crude perlite					Expanded perlite		
	Produced (short tons)	Sold		Used at own plant to make expanded material		Produced (short tons)	Sold	
		Short tons	Value	Short tons	Value		Short tons	Value
1947	10,500	550	$3,000	9,900	$55,000	9,700	7,700	$271,000
1948	22,200	4,400	29,000	17,700	105,000	21,200	18,600	742,000
1949	71,500	27,300	193,000	43,800	317,000	58,100	52,200	2,385,000
1950	110,694	59,802	411,205	41,734	237,957	88,892	86,962	4,741,383
1951	182,260	138,205	615,853	43,383	194,118	134,479	133,175	7,243,298

In 1951 perlite-processing plants were located in 27 States throughout the United States. California led in number of plants with 11, followed by Illinois and Texas with 5 each, and Pennsylvania and Utah with 4 each. There were 1 or 2 plants in each of 22 other States. Some 10 or 12 additional plants were reported to be under construction. As shown in table 13, the largest quantity of expanded perlite was produced and sold by firms in California; large tonnages were also produced and sold in Pennsylvania, Illinois, New Jersey, Oregon, Ohio, and Texas.

TABLE 13.—Expanded perlite produced and sold by producers in the United States, 1950–51, by States

State	1950				1951			
	Produced (short tons)	Sold			Produced (short tons)	Sold		
		Short tons	Value	Average per ton		Short tons	Value	Average per ton
California	20,363	20,179	$1,088,879	$53.96	25,850	25,648	$1,481,428	$57.76
Illinois	11,690	11,690	694,000	59.37	11,978	11,967	692,073	57.83
Pennsylvania	3,743	3,653	237,000	64.88	12,446	12,389	757,060	61.11
Texas	2,314	2,185	106,323	48.66	9,044	8,698	423,730	48.72
Other Western States [1]	27,698	26,481	1,121,530	42.35	32,640	32,584	1,467,831	45.05
Other Eastern States [2]	23,084	22,774	1,493,651	65.59	42,521	41,889	2,421,176	57.80
Total	88,892	86,962	4,741,383	54.52	134,479	133,175	7,243,298	54.39

F. E. Schundler & Co., Inc., Joliet, Ill., completed its new perlite mill at Antonito, Colo. Raw perlite is mined from a deposit in the No Agua Mountains of northern New Mexico, a short distance from the mill. The rated capacity of the plant is 25 tons per hour of crushed, sized, and dried perlite, which was to be shipped to Schundler furnaces in Joliet and Long Island City, N. Y., for processing. Other outlets are in Metuchen, N. J., and West Des Moines, Iowa. This operation was described in detail in the nonmetallics trade press.[21]

Napa Perlite Co., San Francisco, Calif., began mining and crushing perlite on the Holt ranch, near St. Helena, Napa County, Calif.[22] Reserves of crude perlite on this property were said to be about 5 million tons.[23]

Another company, Perlite Aggregates, Inc., was reportedly mining and processing perlite in Conn Valley, near St. Helena, Calif. The deposit being mined was estimated to contain 125 million tons of crude rock. The expanded product was sold for use in plaster and stucco work in the San Francisco area.[24]

The operation of the Florence, Colo., mill of AleXitE Engineering Division, Alexander Film Co., Colorado Springs, Colo., was described in an article. The plant uses crude perlite from deposits near Rosita, which have been in production for several years.[25]

The two major domestic producers of crude perlite, Combined Metals Reduction Co., and Great Lakes Carbon Corp., operated during the year on their deposits at Pioche, Nev., and Socorro, N. Mex. respectively.

The discovery of extensive deposits of perlite near Cordelia, Solano County, Calif., was reported.[26]

A new perlite furnace, which uses the air-flow method of processing, was put on the market.[27] Three patents covering perlite furnaces were issued by the United States Patent Office. One is a bottom-fired, bottom-fed vertical unit,[28] whereas the second is a bottom-fired, side-fed vertical kiln.[29] Both of these furnaces were reported to be in use commercially. A third patent supplemented one issued in 1950.[30]

The press itemized perlite-processing plant developments in Arkansas,[31] Florida,[32] Texas,[33] and Wisconsin.[34] Other articles reviewed processing plant practices of Panacalite Perlite, Inc., Kansas City, Kans.,[35] and Utco Products Co., Salt Lake City, Utah.[36]

The mine value of crude perlite (crushed and sized) averaged $4.46

per short ton in 1951 compared to $6.39 in 1950. This apparent decline was largely due to the practice of assigning low book values to the crude material used by the same firm mining the material. At most perlite mines the price for sized perlite, f. o. b. cars, was between $6.50 and $9.00 per short ton, depending on specifications. The average value of expanded perlite in 1951 was $54.39 per short ton—slightly lower than the $54.52 shown for 1950. In general, the average values increased in the western States and declined in the eastern States.

The Perlite Institute sponsored fire and sound transmission tests on different units of construction;[37] conducted research on perlite concrete mix ratios,[38] strength,[39] thermal conductivity, and the like; published a news periodical, The Perlite Torch; and engaged in other activities in behalf of this growing industry.

Probably 75 percent of the expanded material produced during 1951 was used as a lightweight aggregate in hardwall and fireproofing plasters. About 20 percent was estimated to have been used as aggregate in the production of lightweight concretes,[40] principally poured-concrete roof decks and floor slabs, but increasingly as reinforced backup concrete cast on sheet steel or aluminum to produce large structural panels. Perlite was used as an aggregate for exterior cement stucco work and curtain walls,[41] as a drill mud additive (covered by an applicable patent),[42] in the manufacture of a partition tile,[43] and as a filler in paints, plastics, etc.[44] A patent was issued describing its use as an aggregate with a thermoplastic binder in the production of insulating products.[45]

Miscellaneous applications include: Loose fill; filtration medium; refractory brick; roofing tile; soil conditioner; and numerous lesser special purposes that utilize its light weight, insulating qualities, inertness, or other physical characteristics.

RADIO-GRADE QUARTZ [46]

Orders in 1951 for frequency control units for military communications caused a sharp increase in the consumption of radio-grade quartz and in the number of quartz piezoelectric units produced.

Total imports of uncut quartz crystal increased more than fourfold over 1950. Based on industry advices and interpolation from official Brazilian export statistics, it was estimated that about 66 percent (850,000 pounds) of the total imports was of radio- and optical-grade, and the balance (about 437,000 pounds) was of fusing grade. All of the fusing-grade and over 97.5 percent of the radio-grade quartz crystal imports were from Brazil. Small quantities of radio-grade quartz were imported from France, Japan, Madagascar, and Angola.

The imports from France probably originated in Madagascar, and those from Japan doubtless were surplus stocks from various sources.

Domestic production of radio-grade quartz crystal continued to be negligible. Considerable interest was aroused by the discovery of radio-grade quartz crystal on the Goshute Indian Reservation, Juab County, Utah. The Emergency Procurement Service of General Services Administration contracted for the entire output of the property for 12 months for the National Stockpile, but, after a small pocket of good-quality crystal was mined, production ceased.

The average number of finished piezoelectric units produced per pound of radio-grade quartz, as reported by consumers to the Bureau of Mines, was 11.7 in 1951, compared with 14.1 in 1950 and a peak of 20.3 in 1949. The relatively low yield in 1950 and 1951 was attributed to more rigid military specifications, higher losses during a period of transition to new types of units, and a continuing trend toward the use of smaller crystals from which a fewer number of units per pound of crystal could be cut. The optimum crystal weight for the production of the major part of the units in demand was about 250 grams, compared with 400–500 grams a few years before. Manufacturers used substantial quantities of crystals in the 50- to 100-gram weight range. The small sizes generally are selected on an "eye-clear" basis without further tests for twinning and flaws before slicing into wafers.

The declared value at port of export of the total imports of uncut quartz crystal in 1951 averaged $1.62 per pound, compared with $2.55 per pound in 1950. The value of the radio-grade quartz crystal imports after deducting the estimated quantity and value of fusing-grade quartz (about $0.10 per pound) averaged about $2.40 per pound in 1951 and $3.20 per pound in 1950. The decline in declared value in 1951 reflected the above-mentioned trend toward the use of smaller sizes, rather than changes in the price schedule. In May 1951 the declared value of 80 to 100 gram Brazilian eye-clear faced crystals, f. a. s. port of export, was $0.77 per pound. Faced crystals, 60 to 100 percent usability, 201/300 grams were valued at $4.36 per pound, 301/500 grams at $7.09 per pound, and 501/700 grams at $11.16 per pound.

The Signal Corps continued to sponsor research and pilot-plant work on quartz crystal syntheses and related problems. The Brush Development Co., Cleveland, Ohio, and Bell Telephone Laboratories, Inc., Murray Hill, N. J., both reported significant progress in the hydrothermal synthesis of quartz crystal in autoclaves operated above the critical point of water. The Brush Development Co. reported that pressures of 6,000 p. s. i. at 350° C. were being used.[47] Several articles were published in 1950 and 1951 on various aspects of synthetic quartz crystal growth,[48] as well as a treatise[49] on the principles of crystal growth.

Revised National Stockpile Material Purchase Specifications P–43 for raw quartz crystals for optical and electronic use were issued on September 12, 1951, superseding the issue of June 6, 1950. The most important revision was the lowering of the acceptable usability factor of 100/200 gram crystals from 80 percent for the class formerly designated as S8 to 60-percent usability for the new class L6. Another important change was a decrease in the acceptable minimum area of faced 100/200 gram crystals from ¾ square inch to ¼ square inch. Definitions were clarified, and some changes were made in inspection practices.

TABLE 14.—Imports of uncut quartz crystal, consumption of radio-grade quartz, and production of piezoelectric units in the United States, 1947–51

Year	Imports of uncut quartz crystal [1]		Consumption of radio-grade quartz (pounds)	Production of piezoelectric units [2] (number)
	Pounds	Value		
1947	473,788	$1,815,468	68,100	1,052,400
1948	1,238,820	4,209,531	61,600	1,225,400
1949	319,631	1,462,018	46,200	937,100
1950	310,251	791,412	114,300	1,614,000
1951	1,287,045	2,088,761	282,300	3,290,000

[1] Includes optical-grade quartz used in production of optical instruments.
[2] Includes oscillators, resonators, and other piezoelectric units.

STRONTIUM [50]

No domestic production of strontium minerals had been reported, except possibly sample lots, since 1946. However, it was reported that W. E. Caldwell and George Waterman were planning to explore and mine a deposit of strontium minerals on Fidalgo Island in Puget Sound.[51]

Before 1914 most of the available strontium compounds were produced in Germany. However, during World War I, when German supplies were not available, the United States established domestic facilities for processing ore imported from the United Kingdom. Domestic production of strontium minerals had been sporadic. In the past, some celestite had been mined in Texas for use as a weighting agent in well-drilling muds. Very little had been used for this purpose since the end of World War II.

In 1951 nearly all the strontium minerals consumed in the United States consisted of celestite imported from the United Kingdom and Mexico.

The bulk of the strontium minerals consumed is converted to various chemical compounds. These compounds burn with a characteristic brilliant red flame, and this property is utilized in several pyrotechnical applications—tracer bullets, fireworks, railway and truck fuzees, military flares, and rockets.

In the United States three firms convert strontium minerals into compounds: E. I. du Pont de Nemours & Co., Wilmington, Del.; Foote Mineral Co., Philadelphia, Pa.; and Barium Products, Ltd., Modesto, Calif.

United Kingdom	4,904	86,378	6,655	118,303	11,972	280,392
Total	9,384	176,685	8,630	142,213	14,044	304,504

[1] Strontianite or mineral strontium carbonate and celestite or mineral strontium sulfate.

Strontium metal is produced by King Laboratories, Inc., Syracuse, N. Y., and by Cooper Metallurgical Associates, Cleveland, Ohio. Only a very small quantity is made each year for use principally in removing traces of gases from electronic tubes. Metal Hydrides, Inc., Beverly, Mass., produces strontium hydride on a small scale.

The role of strontium compounds in enameling was described in an article.[52]

Prices.—Nominal prices quoted occasionally during the year for strontium minerals were as follows: Celestite, 92 percent $SrSO_4$, finely powdered, carlots, about $54 per ton; strontianite, minimum 84 to 86 percent $SrCO_3$, lump, carlots, about $55 per ton.

VERMICULITE [53]

The name vermiculite is applied to a group of micaceous minerals that expand or exfoliate to many times their original thickness when heated. It is a very lightweight product for which many industrial uses have been developed.

Production.—Sales of screened and cleaned vermiculite produced in the United States during 1951 showed a slight increase in tonnage and a decrease in value from the previous year.

TABLE 16.—Screened and cleaned vermiculite sold or used by producers in the United States, 1944–51

Year	Short tons	Value	Year	Short tons	Value
1944	54,116	$541,744	1948	138,635	$1,387,233
1945	64,808	648,077	1949	168,819	1,686,419
1946	86,390	867,973	1950	208,096	2,122,427
1947	131,385	1,338,572	1951	209,008	2,093,953

Montana, where production on a commercial scale had been carried on since 1921, continued to be the principal vermiculite-producing State. Near Libby, in Lincoln County, the Zonolite Co. had developed a large deposit.[54] South Carolina was second in order of

Digitized by Google

vermiculite production; several deposits near Travelers Rest in Greenville County are being mined. Production was also reported from North Carolina and Wyoming.

Exfoliation.—Commercial exfoliation of vermiculite is accomplished by passing a graded material through one of the several types of kilns in use. Exfoliation is produced most successfully at temperatures between 1,600° and 2,000° F. The charge is subjected to heat 4 to 8 seconds, followed by rapid cooling, which imparts pliability and toughness to the expanded particles, prevents the scorching or burning of containers, and permits manual handling. The increase in volume, owing to exfoliation, varies from 6 to 20 times that of the unexpanded material. In 1951 some 50 vermiculite exfoliation plants were operating in the United States.

Assuming an average price of $80 a ton for exfoliated material and a 5 percent loss in weight in the exfoliating process, the value of exfoliated and other vermiculite sold in the United States during 1951 would approximate 16 million dollars.

Uses.—Its low bulk density, comparatively high refractoriness, low thermal conductivity, and chemical inertness make vermiculite satisfactory for many types of thermal and acoustic insulation. One of its larger commercial uses is as an aggregate in lightweight concrete, and in the manufacture of prefabricated building units.[55]

Vermiculite aggregate finds an application in hardwall plaster because of its acoustic, thermal-insulating, and fire-resistant qualities; also as a plaster for fireproofing roofs, floors, columns, and steel beams.[56]

Refractory insulation, both in the form of loose vermiculite fill and vermiculite brick, is used in furnaces and kilns.[57]

Its use as a soil conditioner and in hot beds for sprouting seedlings and starting flowers is increasing. A study was made of the qualities imparted to soils by the addition of exfoliated vermiculite.[58]

Unexfoliated vermiculite has a few minor uses, such as when circulated in drilling muds "delaminated" vermiculite is said to assist in sealing off porous formations, thereby lessening the loss of the mud.

Prices.—Domestic screened and cleaned vermiculite in 1951 averaged about $10 a short ton, f. o. b. mines, whereas quotations on South African crude averaged $13.83 a ton, f. o. b. South African shipping points, and some $30 a ton, c. i. f. United States Atlantic ports.

The wholesale price of exfoliated vermiculite continued to average $80 a short ton during 1951. Price to jobbers was usually between 80 cents and $1.10 a 4-cubic foot paper bag, which usually weighed between 24 and 32 pounds. Different grades of exfoliated material sold at slightly different prices.

Africa.—Numerous deposits of vermiculite are known to exist in northern and eastern Transvaal, the largest being in the Palabora

area, some 200 miles by rail from the nearest shipping port of Lourenço Marques. No precise estimate of the reserves of vermiculite in the Palabora area was obtainable in 1951, but it was believed that there are several million tons of marketable material available.[59]

Other Occurrences.—Several promising discoveries of vermiculite in Ontario were reported in the Canadian technical press.[60]

Occurrences of vermiculite were reported from Kenya, Tanganyika, and Nyasaland in Africa; India; Queensland, South Australia; Western Australia; Argentina; Brazil; Japan; and the U. S. S. R.

WOLLASTONITE [61]

Production and sales of a small tonnage of wollastonite were reported from the deposit near Willsboro, N. Y., by the Willsboro Mining Co. Godfrey L. Cabot, Inc., 77 Franklin St., Boston, Mass., acquired this property and took possession late in 1951. Small shipments were made for enamel frit and various ceramic uses. Shipments were made for experimental market development to manufacturers of paint, rubber, plastics, tile, and for metallurgical flux.

Investigation of a ceramic body containing wollastonite, clay, and barium compounds showed a low electrical loss factor.[62]

Formulas for wollastonite bodies and glazes that gave low shrinkage and freedom from crazing and shivering were reviewed.[63]

PART III. STATE REVIEWS

The Mineral Industry of Alaska

By Alfred L. Ransome and William H. Kerns

GENERAL SUMMARY

GOLD continued to be the commodity having the greatest value of output in Alaska in 1951, but a 17-percent decrease in production marked a return to the general downward trend that has characterized the industry since 1947. Despite this decline, the overall value of mineral production gained from $17,852,000 in 1950 to $19,569,000 in 1951, chiefly because of a record tonnage of coal mined (which ranked second in value of production) and a large output of sand and gravel. The mining of platinum continued to be an important factor in the mineral industry, and the production of crude platinum-group metals exceeded that for 1950. Silver output dropped to two-thirds of the total for 1950, and no copper, lead, or zinc was produced. Production of antimony was higher than in 1950, and shipments of ore mined during the year were greater than at any time since 1943. Output of tin was slightly less than in 1950, but the value increased.

TABLE 1.—Mineral production of Alaska, 1949–51

Mineral	1949		1950		1951

Total		15,549,000		17,852,000		19,569,000

[1] Value included with "Undistributed."
[2] Produced in 1950, but not shipped until 1951 from a mine not active in 1951.
[3] Comprises value of pumice (1950–51), stone, platinum-group metals, and minerals whose value must be concealed for particular years (indicated in appropriate column by footnote reference 1).

Although gold mining continued to maintain its position in 1951 as the backbone of the mining industry in Alaska, the situation was becoming increasingly precarious. There was little doubt that if the

Digitized by Google

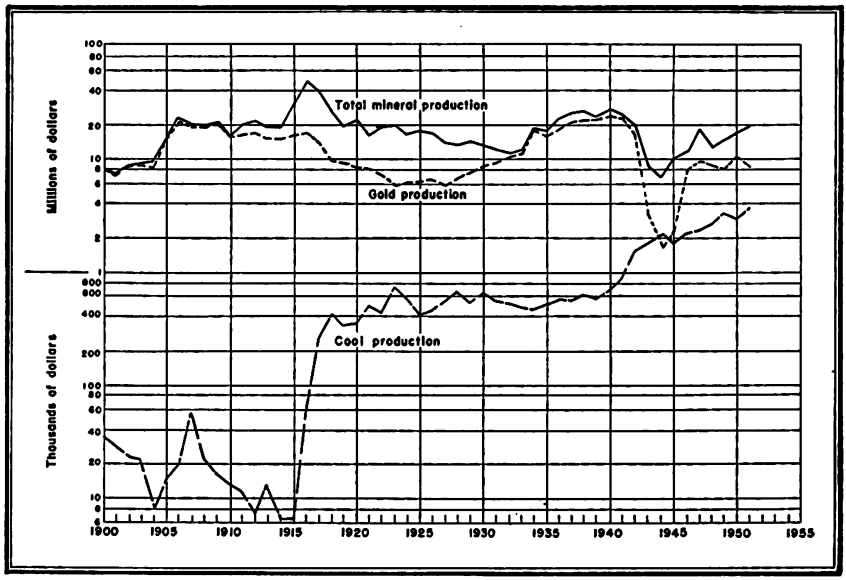

FIGURE. 1.—Value of gold and coal production and of total mineral production in Alaska, 1900–51. From 1911 to 1931 copper production accounted for most of the value of minerals other than gold and coal.

economic factors of high costs and an unchanged established United States Treasury price for gold of $35 per fine ounce continued—and no immediate change in conditions was indicated—the industry would soon relinquish its position as the leader in value of production. Coal, which was second in value of output in 1951, had been rapidly forging ahead as an important commodity; and, if 1951 trends continued as anticipated, it was expected that it would probably reach and might surpass gold as the commodity leader. Although sand and gravel ranked third to gold in 1951 as a value commodity, production had been variable and uncertain, depending upon the number and size of various projects in process of completion in Alaska calling for such materials as road metal for highway construction and aggregate for concrete structures (for civilian use and at military establishments).

Lode mining in the Territory continued to remain virtually at a standstill, with the still-minor exception of antimony and tin; and nonmetalliferous mining—other than coal and sand and gravel—was negligible. Noteworthy with respect to the Alaskan mineral industry was the renewed interest in the critical and strategic minerals during 1951. Although production was negligible or nil, as elsewhere noted, exploration activity and interest shown particularly with respect to chromite, mercury, and nickel (and cobalt) indicated a distinct possibility of active exploitation of these commodities. During 1951 three Government DMA exploration loans were made in Alaska on nickel and cobalt, tin, and tungsten properties; several additional applications for similar loans had been made by the end of the year; and one operating loan was granted for a lode-tin development.

GOLD, SILVER, COPPER, LEAD, AND ZINC

Data on production of gold, silver, copper, lead, and zinc in Alaska, by months in 1951, by years in 1947–51, and totals for 1880–1951, in terms of recoverable metal; the gold production at placer mines, by class of mine and method of recovery; mine production of gold, silver, copper, lead, and zinc, by regions; ore and old tailings sold or treated; and various metallurgical compilations based on output in 1951 are shown in tables 3 to 10, inclusive.

All tonnage figures are short tons and "dry weight"; that is they do not include moisture.

Yardage figures used in measuring material treated in placer operations represent "bank measure"; that is, the material is measured in the ground before treatment. Close control of bank measure is kept by operators of bucket-line dredges, but the quantity of material handled by other placer-mining methods in Alaska is largely estimated by the individual operators on the basis of the square feet of bedrock area worked and the average depth of gravel.

The value of gold, silver, copper, lead, and zinc production reported herein has been calculated at the prices shown in table 2.

TABLE 2.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] (per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

[1] Price under authority of Gold Reserve Act of Jan. 31, 1934.
[2] Treasury buying price for newly mined silver July 1, 1946, to date—$0.9050505 ($0.905 used in 1947 for calculating purposes).
[3] Yearly average weighted price of all grades of primary metal sold by producers. Price in 1947 includes bonus payments by Office of Metals Reserve for overquota production.

Gold.—The recorded production of gold in Alaska in 1951 was 17 percent below the output in 1950 and marked a return to the general downward trend that characterized the industry since the initial postwar upsurge that culminated in 1947. The surprising thing was that production was higher than might have been supposed, considering the adverse economic conditions under which the gold miners continued to operate. Higher-than-ever costs of supplies and equipment, scarcity of equipment and difficulty of obtaining replacement parts and more attractive wage rates offered by contractors connected with defense projects in areas adjacent together posed an almost insurmountable barrier to continued operation of many of the mines. The exceptions included those operations that could be classed as major producers (which, because of large investment in equipment requiring maintenance, have continued operating on a marginal profit or even at a slight loss) or those—large or small—that were fortunate enough to be mining ground rich enough to warrant continued exploitation despite such obstacles, coupled with an unchanged established price of $35 per fine ounce for gold. In 1951 only 6 operations classed

Digitized by Google

as lode-gold mines and 140 placer mines that produced gold were in operation compared with 11 and 216, respectively, in 1950, a startling drop of 36 percent in the total number of operations that produced gold, which had been the economic backbone of the Alaskan mining industry, almost without exception, since mining began there. It was expected that if conditions prevailing in 1951 continued, the downward trend in production of gold probably would be accelerated to the point where a limited output would reflect the work of but a handful of operators in business by virtue of being able to selectively mine a few high-grade deposits. In terms of the future economy of the Territory it was more than likely that the monetary-loss vacuum (in terms of dollar value of output) created by the drop in gold production would be filled—at least in part—by expanding developments of other mineral commodities, such as coal. However, the more serious economic aspect was the probability that marginal deposits of gold—which in the aggregate total many millions of dollars in potential reserves—would never be worked and thus could be considered to be permanently lost as a source of new wealth to the Territory.

The sale of unprocessed or "natural" gold by a few operators who hoped to gain by open-market transactions at prices exceeding $35 per fine ounce apparently was considerably greater in volume than in 1950. The recorded production for 1951 includes 18,082 fine ounces of gold contained in natural gold reported by 3 operators as having been sold on the open market and 825 ounces of gold that was probably sold as natural gold by 2 producers, but not specifically reported as such. One operator reported production of 900 ounces of natural gold, which was not sold. It is possible that some natural gold concerning which no information is available, was produced and sold; the quantities involved are believed to have been relatively small. An undetermined quantity of gold (possibly as much as several thousand ounces) reported sold in 1951—and included statistically in the record for the year—no doubt was produced in 1950, disposed of as natural gold or held speculatively and subsequently sold through the normal channels to the United States mints at the established United States Treasury price. Specific and accurate data regarding natural gold sales are not readily available, and the aforementioned figures giving the number of operators and quantities involved are incomplete. However, from these data it can be assumed that natural gold originating from Alaskan mines and sold in 1951 probably did not exceed 20,000 ounces. Information on prices received for open market sales was not available.

The unusual seasonal limitations to mining activity in Alaska, particularly with regard to placer operations, are indicated by the production of gold in 1951, by months, as shown in table 3. The data are based on mint and smelter receipts that have been adjusted to exclude 3,762 fine ounces of gold received during the first 4 months, which was credited to 1950 production, and to include 13,698 ounces received during the same period in 1952, which is a part of actual output in 1951. Also included and prorated for each month of the active mining season (May through October) was the 18,082 ounces of fine gold contained in natural gold reported sold and the 825 ounces probably sold, all of which did not appear as receipts at mints and

Digitized by Google

smelters. Production was probably somewhat less than shown during the last quarter of the year, particularly for December, but correspondingly higher for the period June through September, which represents the average season for greatest activity in mining in the Territory between the spring breakup or thaw and the fall freeze. The principal reason for the relatively high receipts at mints and smelters during the last 3 months is that numerous operators make their gold "cleanup" only once or twice during the active mining season; as a result, a substantial quantity of gold accumulated in the sluices over a period of several months is not recovered until late fall and often not reported as receipts at the mint or smelter until the following spring.

TABLE 3.—Mine production of gold, silver, copper, lead, and zinc in Alaska in 1951, by months, in terms of recoverable metal [1]

Month	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)
January	278	64			
February [2]	82	1,766	1	21	1
March	311	81			
April	1,313	78			
May	7,779	1,159			
June	17,104	2,266			
July	32,965	4,072			
August	51,671	6,866			
September	48,543	6,181			
October	46,617	5,894			
November	18,175	2,496			
December	14,799	1,947			
Total	239,637	32,870	1	21	1

[1] Derived mostly from mint and smelter receipts; data are adjusted to exclude receipts during the first part of 1951 previously credited to 1950 production and to include receipts in 1952 that are a part of actual output in 1951.

[2] Includes 35 ounces of gold, 1,756 ounces of silver, 1 ton of copper, 21 tons of lead, and 1 ton of zinc actually mined in December 1950 but not shipped until 1951, from a mine not active in 1951.

The 15 leading gold-producing mines (all placer) in Alaska in 1951, listed in the accompaning tabulation, yielded 83 percent of the total recorded gold output of the Territory; the 5 leading producers (all using bucket-line dredges) supplied 67 percent. The Fairbanks district in the Yukon River Basin region and the Nome district in the Seward Peninsula region ranked first and second, respectively, in gold production in the Territory because of the bucket-line dredging operations of the United States Smelting, Refining & Mining Co.

Active mining at lode-gold mines in interior Alaska was limited to 1 mine, the Fern, in the Willow Creek district, operated by the Black Butte Mining Co., Inc. In Southeastern Alaska the LeRoy Mining Co. was active during the season at the Rainbow mine at Glacier Bay in the Juneau district. Small quantities of gold were recovered by reworking old tailings and mill cleanups at the Big Hurrah mine, Nome district, Seward Peninsula region; Gold Cord mine, Willow Creek district, Cook Inlet-Susitna region; and the Alaska Empire mine, Admiralty Island district, Chichagof mine, Chichagof Island district; and the Alaska Juneau mine, Juneau district, Southeastern Alaska region.

[1] Includes recoverable metal content of gravel washed (placer operations), ore milled, old tailings or slimes re-treated, and ore shipped to smelters during calendar year indicated.
[2] Does not include gravel washed.
[3] "Mines producing" includes all and only those mines known to have produced in 1951, for some of which no production data are included since such data are not available. However, 1951 production figures include a small amount of production known to have occurred in prior years.
[4] Excludes quantity of ore (included in 1950 figure) from which a small tonnage of concentrate shipped in 1951 was produced, recoverable content of which concentrate is included in 1951 production of metals shown.
[5] Figure not available.

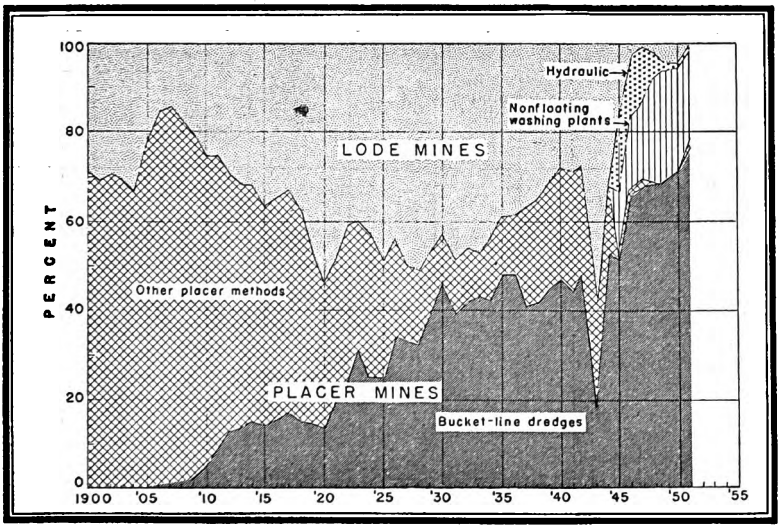

FIGURE 2.—Percentage of total Alaska gold produced at lode and placer mines and by various methods of placer mining, 1900–51; "other placer methods" includes hydraulic and nonfloating washing plants for which separate data are not available before 1943.

Silver.—The 32,870 fine ounces of silver credited to 1951 production (a 38-percent decrease from 1950) was almost entirely the byproduct of gold mining (95 percent); the remainder was lead ore. The most important producer of silver in Alaska in 1951 was the United States Smelting, Refining & Mining Co., which recovered silver as a byproduct of bucket-line dredging operations in the Fairbanks and Nome districts. The Riverside mine, a substantial producer of silver as a byproduct from lead ore in 1950, did not operate during 1951. The small percentage of silver from lead ore credited to 1951 came from this property; the material was produced in 1950 but not shipped until 1951.

Copper, Lead, and Zinc.—There was no production of any of the base metals (copper, lead, and zinc) in Alaska in 1951. The relatively minor output credited to 1951 came from ore produced at the Riverside mine near Hyder in Southeastern Alaska in 1950 but not shipped until 1951; the mine was inactive during 1951. In the Nizina district, Copper River region, extensive prospecting was in progress on the Nelson and Radovan copper claims near McCarthy during 1951. An investigation of Kasna Creek copper prospect, Bristol Bay region, by the Bureau of Mines was described in a report published in 1951.[1]

MINING INDUSTRY

Bucket-line dredges (23 in 1951 compared with 28 in 1950) washed 84 percent of the total gravel mined for gold in Alaska in 1951 and recovered 78.5 percent of the placer gold, and 78 percent of the total gold (lode and placer). Placer mining produced 99.5 percent of the total gold output in Alaska in 1951 (96 percent in 1950). No dragline dredges (which include all operations using a floating washing plant and a dragline excavator) were reported in operation during 1951. Several so-called dry-land dredges (which include a power excavator and movable mechanical washing plant, both of which are on dry land) were operated at widely separated localities in the Territory during the year. Placer operations using combinations of bulldozer and hydraulic methods—in many cases supplemented with dragline equipment—were less in number than in 1950, but the mining method employed continued to be the preferred one in the Territory. In general, the gold-bearing material is bulldozed from the cut to the sluice boxes (or sluice plate, at the head of the sluice box, on which the gravel is dumped or pushed) and then washed through by the use of a hydraulic giant or other means of directing and controlling the flow of water. In many cases where the supply of water is unsufficient, it is utilized in a closed-circuit system, with a settling pond downstream below the sluices and a pump for return of the water. Dragline equipment—when used—is generally employed for disposing of tailing and in some cases for transporting gravel to elevated sluice boxes or washing plants. Occasionally draglines or bulldozers are used for removing overburden, but by far the greatest proportion of the overburden, in the form of frozen "muck," is washed off with hydraulic giants. The automatic hydraulic giant—"Intelligiant"—recently developed and first used during 1950, has been continually improved and has been found particularly useful in some areas under certain conditions for the purpose of disposing of frozen overburden. In 1951, combination methods of placer mining, in which gravel was moved by mechanical means to the washing plant or sluice box (classified as nonfloating washing plants), washed 15 percent of the total gravel mined and recovered 20 percent of the placer gold, a 46-percent decrease in gravel handled and a 31-percent decline in gold recovered compared with 1950; 84 such operations were active in 1951 (116 in 1950). Operations in which gold was recovered primarily by hydraulic methods (excluding hydraulic stripping of overburden) again showed a decrease in the number of mines, but the quantity of gravel washed and gold recovered increased 23 and 33 percent, respectively, above comparable totals for 1950. Gold output from a smaller number of small-scale hand operations increased 13 percent over 1950. Four drift mines produced only a small quantity of gold in 1951, but available reported data indicate that the average value per cubic yard of the ground worked by drifting was substantially higher than usual in 1951. The total yardage of gravel washed at gold placer mines decreased only 1 percent, whereas the gold recovered was 14 percent less than in 1950. The average recoverable gold content of gravel decreased 13 percent.

Digitized by Google

Activity at lode mines (gold, silver, copper, lead, and zinc) in Alaska in 1951 was conspicuous by its absence. Of the 6 operations included in the lode classification, only 2 actively mined and milled ore. The tonnage of material from lode-gold mines (no base-metal mines were operated) in Alaska treated in 1951 was 77 percent less than in 1950. The output of lode gold dropped 91 percent to the point where the total of 1,110 fine ounces recovered from the active lode mines, tailings re-treated at inactive mines, and mill cleanups comprised only 0.5 percent of the Territory total (lode and placer).

ORE CLASSIFICATION

All 13,870 tons of lode material (including 450 tons of ore and 13,420 tons of old tailing) sold or treated in 1951 was classed as dry gold ore. Definitions used in ore classification are given in the Gold and Silver chapter of this volume.

TABLE 8.—Mine production of gold, silver, copper, lead, and zinc in Alaska in 1951, by class of ore or other source material, in terms of recoverable metal

Source	Number of mines [1]	Material sold or treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore:							
Dry gold	4	[2] 450	601	128			
Lead		(3)	36	1,783	1,600	42,000	1,200
Other "lode" material: Old tailings [4]	2	13,420	473	111			
Total "lode" material	6	[5] 13,870	1,110	2,022	1,600	42,000	1,200
Gravel (placer operations)	140		238,527	30,848			
Total, all sources	146	[5] 13,870	239,637	32,870	1,600	42,000	1,200

[1] "Number of mines" includes all and only those mines known to have produced in 1951, for some of which no production data are included since such data are not available. However, production figures include a small amount of production known to have occurred in prior years.
[2] Does not include ore from which 115 ounces of gold and 64 ounces of silver were recovered.
[3] Ore reported in previous year, concentrates shipped in 1951.
[4] Dry gold.
[5] Excludes ore indicated in footnotes 2 and 3.

METALLURGICAL INDUSTRY

All the total ore and old tailings handled during 1951 was treated at mills (with or without concentrating equipment); no ore was shipped for direct smelting. Of the lode gold produced, 58 percent was recovered by amalgamation and 6 percent by cyanidation, largely from the re-treatment of tailings at inactive mines. Smelters in the United States received only 100 tons of concentrates (30 tons gravity, and 70 tons flotation) for smelting from Alaska operations of mines producing gold and lead (with silver, copper, and zinc as by-products). One shipment of concentrate (containing the base metals and some silver) originated from lead ore produced at the Riverside mine near Hyder, Southeastern Alaska, in 1950 and reported in that year.

REVIEW BY REGIONS

COOK INLET-SUSITNA

Because 2 major producers ceased operations at the close of the 1950 season, the total value of gold output from the Cook Inlet-Susitna region for 1951 was only 7 percent of that for 1950. The Alaska Pacific Consolidated Mining Co. closed the Independence lode-gold mine on Fishhook Creek in the Willow Creek district in January 1951 after being active since late in the season of 1949. Collinsville Mines (dry-land dredge with dragline equipment) on Mills Creek, which had been the largest producer in the Yentna-Cache Creek district for the previous 3 years, was not operated during 1951.

The small quantity of gold produced in the Cook Inlet-Susitna region in 1951 was recovered from 2 lode operations in the Willow Creek district and 7 placer operations in the Yentna-Cache Creek district.

Willow Creek District.—The Black Butte Mining Co. operated the Fern mine on Archangel Creek (under lease from the Fern Gold Mining Co.) throughout 1951. From 210 tons of gold ore treated in the 50-ton mill on the property, 270 ounces of gold and 15 ounces of silver were recovered by amalgamation. Renshaw & Brown did annual assessment work at the Gold Cord mine on Fishhook Creek and operated the 20-ton amalgamation-flotation mill for 15 days during August 1951. From 50 tons of gold ore and 150 tons of tailing milled, 45 ounces of gold and 6 ounces of silver were recovered as bullion by amalgamation; in addition, 3 tons of concentrate (containing 20 ounces of gold, 1 ounce of silver, and 7 pounds of copper), produced by flotation, was shipped to a smelter in the United States.

Yentna-Cache Creek District.—The largest producer of gold in the Yentna-Cache Creek district in 1951 was Mike Trepte, who operated on Bird Creek (under lease from the Alaska Exploration & Mining Co.) and recovered a moderate quantity of gold and silver by hydraulicking. Several other operators recovered small quantities of gold by small-scale hand and hydraulic methods.

Digitized by Google

COPPER RIVER

Of the 4 mines reported producing during 1951 in the Copper River region, all were placer-gold operations, 2 in the Chistochina district and 2 in the Yakataga district. The largest producer in the region was the Mount Kimball Construction Co., which operated on Slate Creek in the Chistochina district and recovered a substantial quantity of gold by a hydraulic-dragscraper-bulldozer combination method. Two operators, Eugene and Harvey Cline and B. B. Watson, recovered a moderate quantity of gold from the Yakataga Beach in the Yakataga district by small-scale hand methods.

KUSKOKWIM

Eight placer-gold mines were reported producing in the Kuskokwim region in 1951, with a total value of gold output equal approximately to that of 1950. Four-fifths of the gold produced in the region was recovered from 5 operations in the Tuluksak-Aniak district; the remainder came from 2 operations in the McGrath district and 1 in the Goodnews Bay district.

Goodnews Bay District.—The Goodnews Bay Mining Co. produced a moderate quantity of gold as a byproduct from crude platinum mined on the Salmon River by bucket-line dredging and by a hydraulic-bulldozer-dragline combination.

McGrath District.—Strandberg & Sons operated a flume-type bucket-line dredge on Candle Creek and produced more gold in 1951 than in 1950. This was a remarkable record, considering the difficult conditions under which they were working. A Government contract in the vicinity with a higher wage scale than a gold-mining operation could pay made it impossible for this operation to hire enough men to strip the ground ahead of the dredge. This necessitated turning away from virgin ground and reworking old tailing that had been previously dredged.

Tuluksak-Aniak District.—The New York Alaska Gold Dredging Corp., the largest gold producer in the region and the third largest in the Territory in 1951, as in 1949 and 1950, operated 2 electrically powered floating bucket-line dredges—1 on California Creek equipped with eighty 6-cubic-foot buckets and 1 on the Tuluksak River equipped with sixty-five 1½-cubic-foot buckets. Taylor Creek Placers recovered a substantial quantity of gold using a dragline-bulldozer-hydraulic combination with nonfloating washing plant on Taylor Creek. Three other operations in the district, Canyon Creek Mining Co. on Canyon Creek, Donlin Placers on Snow Gulch, and Russell Schaefer on Forty-Seven Creek, recovered a moderate quantity of gold using bulldozer-hydraulic combinations with nonfloating washing plants.

Tolovana		5			11,458	11,458	1,050				401,980
Other districts [7]		23			13,934	13,934	1,149				488,730
Total Alaska	6	140	[8] 13,870	1,110	238,527	239,637	32,870	1,600	42,000	1,200	8,424,915

[1] Only those districts shown separately for which Bureau of Mines is at liberty to publish figures; others producing listed in footnote 7 and their output included with "Other districts."

[2] Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property. Includes all and only those mines known to have produced in 1951 for some of which no production data are included since such data are not available. However, production figures include a small amount of production known to have been made in prior years.

[3] Sources of total silver as follows: 2,022 ounces from lode mines, and 30,848 from placers.

[4] Property not active; production was before, but not reported until 1951.

[5] Excludes ore from which 105 ounces of gold and 19 ounces of silver were produced. This ore was reported in figures for 1950; concentrate was shipped in 1951.

[6] Ore reported in previous year; concentrate shipped in 1951.

[7] Includes the following districts for which quantities and values cannot be shown separately (number of operations in parenthesis): Chistochina (2) and Yakataga (2), Copper River region; Goodnews Bay (2) and McGrath (2), Kuskokwim region; Kiana (1) and Shungnak (1), Northwestern Alaska region; Council-Bluff (2), Koyuk (2), and Port Clarence (1), Seward Peninsula region; Bonnifield-Nenana (1), Chandalar (2), Eagle (2), Hughes (1), Kantishna (1), and Melozitna (1), Yukon River Basin region.

[8] Excludes ore indicated in footnotes 5 and 6.

Digitized by Google

NORTHWESTERN ALASKA

Only 2 mines reported producing gold in the Northwestern Alaska region in 1951; Helcolican Mines, Inc., on Klery Creek in the Kiana district, operated a flume-type floating bucket-line dredge equipped with fifty-four 3-cubic-foot buckets, and Tronstad & Goodwick on Dahl Creek in the Shungnak district recovered a small quantity of gold by hydraulicking.

SEWARD PENINSULA

One-quarter of the Alaska placer-gold output in 1951 came from the Seward Peninsula region. Seven floating bucket-line dredges were operated in the region during 1951, 5 less than in 1950. Surprisingly, the total gold output for the region for 1951 was only 10 percent less than for 1950. Two-thirds of the gold produced in the region in 1951 came from the Nome district, where 4 floating bucket-line dredges were in operation. Two floating bucket-line dredges were operated in the Fairhaven district and one in the Council-Bluff district. Twenty-three other mines reported producing gold in the region in 1951 using hydraulic giants, bulldozers, dragline excavators, and small scale hand tools, either separately or in combination.

Council-Bluff District.—The Alaska Placer Co. operated a bucket-line dredge equipped with sixty 3-cubic-foot buckets on the Niukluk River from June 12 to October 4, 1951. Sourdough Dredging Co., formerly a substantial producer of gold by bucket-line dredging, did not report any production during 1951. The history of the "Sourdough" dredge, formerly known as the "Wild Goose," and its 41 years of operation on Ophir Creek were given in an article published in 1951.[2]

Fairhaven District.—The Casa de Paga Gold Co., operating 2 bucket-line dredges on the Inmachuk River from June 1 to October 15, 1951, was the largest producer of gold in the Fairhaven district and second largest in the region. Ranking second as a producer of gold in the district, the Candle Creek Mining Co. recovered a substantial quantity of gold from Candle Creek, using a dragline-bulldozer-hydraulic combination. Bernard & Dahl Exploration Co. on Bear Creek recovered a moderate quantity of gold, using a bulldozer-hydraulic combination with nonfloating washing plant.

Kougarok District.—Because of the shutdown of 4 major operations in the Kougarok district, the total gold production for 1951 was only about one-third of the previous year's output. Kougarok Consolidated Placers, Inc., the largest producer of gold in the district in 1950 (using a dragline-bulldozer-hydraulic combination), was inactive during 1951 (its bucket-line dredge was not operated during either year). Three bucket-line dredges, which were operated in the district in 1950 by the Gold Dust Mining Co. on the Kougarok River, North Fork Dredging Co. on Harris Creek, and Tolbert Scott & Son on Iron Creek, were inactive during 1951. N. B. Tweet & Sons bulldozer-hydraulic combination operation on claims 6 and 7 below Johnson's Discovery, Mascot Gulch (under lease from M. J. Walsh), was the largest producer of gold in the district in 1951. This

[2] Mining World, Wild Goose Makes Trip No. 3: Vol. 13, No. 8, July 1951, pp. 20-21.

Digitized by Google

property was worked by Noonan and Whitmore in 1950. Atlas Mines (George J. Waldhelm), operating on Atlas Creek with a dragline-bulldozer-hydraulic combination, washed 4,380 cubic yards of gravel from June 1 to October 1, 1951, to recover 225 ounces of gold and 24 ounces of silver. Lyman H. Madden recovered 108 ounces of gold and 11 ounces of silver by using a bulldozer-hydraulic combination with nonfloating washing plant on Garfield Creek during 1951. Other producers of a moderate quantity of gold in the district in 1951—all using combinations of dragline-bulldozer-hydraulic equipment—were Patrick J. Bliss on claim 8 on Quartz Creek, Grant Mining Co. on Coffee Creek, Trinity Mining Co. (Kanari & Carey) on Trinity Creek, and Wirum Bros. on Dome Creek.

Koyuk District.—The major producer in the Koyuk district in 1951, as in 1950, was the J. E. Baldwin and C. T. Moon operation on the Right Fork of Sweepstake Creek, where a substantial quantity of gold was recovered using bulldozer-hydraulic equipment.

Nome District.—Two-thirds of the gold produced in the Seward Peninsula region in 1951 came from the Nome district, where 4 floating bucket-line dredges were in operation. The United States Smelting, Refining & Mining Co. (Nome unit), operating 3 of its fleet of 4 bucket-line dredges in the vicinity of Nome from May 15 to November 23, 1951, was the largest producer of gold in the Nome district and Seward Peninsula region and ranked second in the Territory in 1951. The three dredges operated are electrically powered and equipped with 134, 109, and 78 9-cubic-foot buckets. Lee Bros. Dredging Co., the second largest gold producer in the district in 1951, operated 1 of its 2 bucket-line dredges on the Solomon River from June 17 to November 13, 1951. The dredge operated is the flume type, diesel-powered, and equipped with seventy-five 5-cubic-foot buckets. Other smaller operations in the district in 1951 used various combinations of power excavators, hydraulic equipment, and hand tools to recover a small quantity of gold.

Port Clarence District.—A small quantity of gold was recovered in 1951 as a byproduct of tin placer mining on Buck Creek by the Northern Tin Co. using dragline-bulldozer-hydraulic equipment.

Serpentine River District.—George Bodis recovered 113 ounces of gold and 13 ounces of silver from 4,500 cubic yards of gravel washed on Dick Creek, using bulldozer-hydraulic equipment with a nonfloating washing plant.

SOUTHEASTERN ALASKA

Half of the total Alaska lode-gold output reported in 1951 came from 4 operations in the Admiralty Island, Chichagof Island, and Juneau districts of the Southeastern Alaska region. Of these operations, 3 were either mill cleanup or re-treatment of old tailing; the LeRoy Mining Co. operation at the Rainbow mine on Reid Inlet in Glacier Bay in the Juneau district was the only active mine. The total gold output from lode operations for 1951 in the Southeastern Alaska region was only one-sixth of that for 1950. No gold placers were reported active in the region in 1951. The Riverside mine in the Hyder district, which had been the only producer of lead (with a substantial quantity of copper and some zinc recovered as byproducts) in the Territory for a number of years, was not operated

Digitized by Google

in 1951. A shipment of lead concentrate from the Riverside mine to a smelter in the United States in 1951 was produced from ore mined in 1950.

Admiralty Island District.—A total of 110 ounces of gold and 25 ounces of silver was recovered in 1951 as bullion and from concentrates shipped to a smelter in the United States from treatment of old tailing and a mill cleanup at the Alaska Empire Gold Mining Co. lode mine at Hawk Inlet on Admiralty Island preparatory to installing a new mill equipment.

Chichagof Island District.—Hayes & Whitely Enterprises recovered 151 ounces of gold and 38 ounces of silver (as bullion from amalgamation, and from gravity concentrate shipped to a smelter in the United States) from treatment of 100 tons of old tailing from the Chichagof mine on Chichagof Island during 1951.

Juneau District.—The Alaska Juneau mine at Juneau remained inactive during 1951. Hayes & Whitely Enterprises re-treated 13,020 tons of old tailing and recovered 196 ounces of gold and 35 ounces of silver by amalgamation; 3 tons of gravity concentrate (containing 57 ounces of gold, 28 ounces of silver, 11 pounds of copper, and 465 pounds of lead) was shipped to a smelter in the United States. The LeRoy Mining Co. operated the Rainbow mine in Glacier Bay from June through September 1951, and treated 15 tons of gold ore in an 18-ton gravity-concentration mill on the property. Table concentrate was amalgamated to recover 41 ounces of gold and 17 ounces of silver. The LeRoy Mining Co. was dissolved following the termination of mining on this property at the close of the 1951 season.

YUKON RIVER BASIN

Ninety-one gold-placer-mine operators in 17 districts in the Yukon River Basin region produced 66 percent of the total Alaska gold output in 1951. Eleven bucket-line dredges operating in the Yukon River Basin supplied 74 percent of the placer gold produced in the region and 49 percent of the placer gold produced in the Territory. The Fairbanks district continued to be the most important placer-gold-producing area in the region, furnishing 42 percent of the total placer-gold output recorded in the Territory. No lode-gold operations were reported active in the region in 1951.

Circle District.—Two bucket-line dredges were active in the Circle district during 1951. Gold Placers Inc., operating its diesel-powered dredge (equipped with sixty 4-cubic-foot buckets) on Coal Creek from April 15 to October 15, and C. J. Berry Dredging Co. operating its diesel-powered dredge on Lower Mammoth Creek from June 14 to October 19 ranked first and second respectively, in total gold output in the Circle district in 1951. The P. R. & H. Mining Co. followed in third place; 2,063 ounces of gold and 456 ounces of silver were recovered from 80,000 cubic yards of gravel washed from June to October from Lower Deadwood Creek, using a bulldozer to deliver gravel to bedrock sluice boxes. The company reported this to be the last season's activity at this location. R. R. Wilkinson on Miller Creek produced a moderate quantity of gold, using a bulldozer-hydraulic combination method of mining. Eight other placer operations in the Circle district produced small quantities of gold, using hydraulic or bulldozer-hydraulic combination methods.

Digitized by Google

Eagle District.—The Yukon Placer Mining Co., using bulldozer equipment, operated on Fourth of July Creek in the Eagle district from April 20 to September 12, 1951, and recovered a substantial quantity of gold. The company did not plan to operate the property in 1952. B. F. Hansen on Alder Creek recovered a moderate quantity of gold using a bulldozer-hydraulic combination.

Fairbanks District.—The United States Smelting, Refining & Mining Co. (Fairbanks unit) operated 5 bucket-line dredges in the Fairbanks district in 1951 and—as in previous years—was by far the largest producer of gold, not only in the district but in the Territory. The electrically powered dredges included three 6-cubic-foot Bethlehem, one 10-cubic-foot Bethlehem, and one 10-cubic-foot Yuba. The dredges were located near Fairbanks on Cripple, Engineer, Little Eldorado, and Fairbanks Creeks and Gold Hill, a bench on the Left Limit of Ester Creek. The dredge operated on Eva Creek during the 1950 season was moved 1¼ miles through a prepared channel to the Gold Hill bench at the beginning of the 1951 season. Other than the dredges, the company used 197 J-Hendie No. 2 hydraulic giants and an electrically powered Bucyrus 10W 8–12 cubic-yard dragline to remove over 8 million cubic yards of overburden.

Brinker-Johnson Co., the second largest producer of gold in the Fairbanks district and third largest in the Yukon River Basin region in 1951, operated its Walter W. Johnson Co. diesel-powered bucket-line dredge on Caribou Creek from June 12 to October 31. It was reported that this company completed repayment of the Reconstruction Finance Corporation loan during the 1951 season.

Of the producers of gold from placer mines using combination of dragline, bulldozer, and hydraulic equipment in the Fairbanks district in 1951, the Alder Creek Mining Co. operation on Fairbanks Creek was the largest and ranked third in the district among all placer operations. From 133,330 cubic yards of gravel washed between May 15 and October 15, 3,230 ounces of gold and 476 ounces of silver were recovered. The Wolf Creek Mining Co. on Wolf Creek was the fourth largest producer of gold in the district in 1951. A bulldozer was used to dig and deliver gravel to a 1½-cubic-yard Bucyrus diesel-powered dragline, which in turn delivered it to an elevated sluice box. Other producers of smaller quantities of gold in the district using various combinations of dragline, bulldozer, and hydraulic equipment were Hassel & Sticha on Ready Bullion Creek, R. V. Watkins at Hope mine on Faith Creek, Helmer Johnson on Cleary Creek, N. O. Kupoff on Pedro Creek, E. L. Maurer on First Chance Creek, Wickstrom & Co. on Gilmore Creek, and Fred Wildt on Homestake Creek.

Fortymile District.—The total gold output from the Fortymile district in 1951 (only 58 percent of that for 1950) was reported produced from 8 operations. The Wade Creek Dredging Co. on Wade Creek ranked first in total gold output in the district in 1951. At the close of the 1951 season the company discontinued operations on this property, and it was stated that equipment was being moved into Canada because conditions are more favorable for placer mining. The Franklin Mining Co. operation (dragline-bulldozer-hydraulic) on claim 2 below Discovery on Chicken Creek from June 1 to September 15 ranked second in production of gold in the district in 1951.

Digitized by Google

Other operators in the district that recovered 100 ounces or more of gold from placers worked by various combinations of dragline-bulldozer-hydraulic equipment were (in order of output): Uhler Creek Mining Co. on Stonehouse Creek, Squaw Creek Mining Co. on Squaw Creek, William Meldrum on Chicken Creek, and Purdy Bros. on claim 2 on Myers Fork. Purdy Bros. recovered 155 ounces of gold and 26 ounces of silver from 1,116 cubic yards of gravel washed between June 1 and August 10, 1951.

Hot Springs District.—The two largest producers of gold reported in the Hot Springs district in 1951, both bulldozer-hydraulic operations, were Enstrom & McDougal on American Creek and A. W. Pringle on Rhode Island Creek. Enstrom & McDougal did not operate the American Creek property during the 1950 season. Peter Johnson on Glenn Gulch and Tony Lanning on Omega Creek each produced a small quantity of gold using bulldozer-hydraulic combinations with nonfloating washing plants. L. McGee purchased the property formerly owned and operated by Cleary Hill Mines Co. on Sullivan Creek and Tofty Gulch. Although a large part of the summer was spent on development work, a moderate quantity of gold was recovered, using bulldozer-dragline elevated sluice-box equipment. Larson & Berg recovered a small quantity of gold by deep drift mining on Woodchopper Creek.

Hughes District.—The only producer of gold reported active in the Hughes district in 1951 was the Strandberg & Sons operation on Indian River. A substantial quantity of gold was recovered using dragline-bulldozer equipment with a dry-land washing plant. As an example of one major factor that contributes to the high cost of mining in Alaska, diesel oil for the equipment was air-freighted from Tanana 80 miles to the Utopia Creek Airfield, then hauled by trailer and bulldozer from the field 8 miles to the property.

Iditarod District.—North American Dredging Co., the largest producer of gold in the Iditarod district in 1951, as it had been for the past 3 years, operated its diesel-powered bucket-line dredge equipped with seventy 3½-cubic-foot buckets on the Mohawk Association property on Otter Creek. Miscovich Bros. operation on Discovery claim on Otter Creek, using bulldozer, hydraulic lift, hoe shovel, and hydraulic equipment, was the second largest producer of gold in the district. Patrick Savage, on the Alpha Association ground on Flat Creek, recovered 931 ounces of gold and 115 ounces of silver from 50,000 cubic yards of gravel, using a dragline-bulldozer-hydraulic combination from May 2 to October 10, 1951. The Happy Placers (John Bouquier, owner), using bulldozer equipment, worked on Happy Creek from June 1 to October 6 and recovered 408 ounces of gold and 62 ounces of silver from 8,000 cubic yards of gravel. Other placer operations producing 100 ounces or more of gold in the district in 1951 were Gust Backstrom on Flat Creek, Hatton & Turner on Willow Creek, and Prince Creek Mining Co. on Prince Creek.

Innoko District.—The Colorado Creek Mining Co. operation on Colorado Creek (using dragline-bulldozer equipment) was the largest producer of gold in the Innoko district in 1951, and the Uotila and Hard operation on claims 2 and 3 above Upper Discovery on Ophir Creek (using dragline-bulldozer-hydraulic equipment) ranked second. The Innoko Dredging Co. operated a diesel-powered bucket-line dredge

Digitized by Google

(equipped with forty-five 3½-cubic foot buckets) on Ganes Creek from May 15 to October 23, 1951. During part of the year the dredge reworked old tailing that had been dredged previously. Rosander & Reed worked placer ground on Yankee Creek, using dragline-bulldozer-hydraulic equipment, from April 22 to October 10 and recovered 1,934 ounces of gold and 223 ounces of silver from 238,000 cubic yards of gravel. Other placer operations in the district in 1951 that produced substantial quantities of gold, using various combinations of dragline-bulldozer-hydraulic equipment, were J. A. Degnan Mining Co. on Lower Little Creek, Gurtler & Myklebust on Little Creek, Eric Hard on Cripple Creek, Hugh Matheson & Co. on Spruce Creek, and Victor Creek Mining Co. on Victor Creek.

Kantishna District.—Hosler Mines operated on Moose Creek at the mouth of Eureka Creek from June 15 through September 1, 1951, using bulldozer-hydraulic equipment.

Koyukuk District.—Total gold production from 11 placers in the Koyukuk district in 1951 was only 10 percent of the 1950 output. No one operation reported gold recovery over 100 ounces.

Marshall District.—Lars Ostnes operated on Willow Creek in the Marshall district during 1951, using dragline-bulldozer-hydraulic equipment, and reported recovery of 403 crude ounces of gold.

Melozitna District.—The Iditarod Operating Co. produced a substantial quantity of gold from Golden Creek in the Melozitna district in 1951, using bulldozer-hydraulic equipment.

Rampart District.—The major part of the gold output in the Rampart district in 1951 was produced by the Little Minook Mining Co. on Little Minook Creek, using dragline-bulldozer-hydraulic equipment. It was reported that 60,000 cubic yards of gravel was washed to recover 1,380 crude ounces of gold. Other placer-mine operations in the district in 1951 were Swanson Bros. on Hunter Creek and Pioneer Mining Co. on Hoosier Creek.

Ruby District.—The Miscovich Bros. operation on Flat Creek was the largest producer of gold in the Ruby district in 1951. Automatic giants (a type invented and developed by John Miscovich) were used for stripping overburden. Bulldozers were used for digging and delivering gravel to a sump, where it was hydraulically lifted to an elevated sluice box. Tailing was stacked with a dragline, slime and excess water being discharged to the drain by a hydraulic lift and pump. The Long Creek Mining Co. operation on claim 8 above Discovery and Boston Bench on Long Creek produced a substantial quantity of gold, using a dragline-bulldozer-hydraulic combination. Using the bulldozer-hydraulic mining method, the Granite Creek Mining Co. recovered a substantial quantity of gold from Ophir Creek. Leonard Zaiser operated a drift placer mine on Timber Creek.

Tolovana District.—The Callahan Zinc-Lead Co. operated a floating bucket-line dredge on Livengood Creek in the Tolovana district under a working agreement with the Reconstruction Finance Corporation from May 17 to October 17, 1951. The diesel-powered dredge is equipped with eighty-eight 6-cubic-foot buckets. Olive Creek Mines, using dragline-bulldozer-hydraulic equipment on Olive Creek, was the second largest producer of gold in the district in 1951. Other operators in the district, all producing 100 ounces or more of gold and using various combinations of dragline-bulldozer-hydraulic equipment

Digitized by Google

either together or separately, were Four A. Mining Co. on Sumner Creek, John Radak on Ruth Creek, and Warwick Mines on Gertrude Creek.

OTHER MINERALS

Antimony.—Considerable interest in antimony was shown in 1951, and shipments of ore mined during the year were higher than at any time since 1943. The marked increase over the 1950 output was due mainly to the activity of Alamco, Inc., of Fairbanks, which productively operated 2 properties under lease during the year, the Sawtooth Mining Co. Sawtooth mine near Rampart, and Sam Gamblin's Rambler mine on Boulder Creek in the Tok district, both in the Yukon River Basin region. The largest output in the Territory was from the Sawtooth mine. However, all of that mine's ore was still stockpiled at the end of the year, awaiting favorable conditions for freighting overland by tractor train to Livengood and hence by truck to the railhead at Fairbanks. Of the smaller quantity of lower grade ore mined from the Gamblin property, most was shipped to a smelter in the United States. Some development work was undertaken by Alamco at an antimony property at Smith Creek near Wiseman; a few tons of ore was mined but not shipped.

Earl R. Pilgrim & Co. again operated the Stampede mine in the Kantishna district, Yukon River Basin region. A substantial tonnage of 53-percent ore was freighted by plane to Nenana for transshipment to a smelter in the United States.

Coal.—Coal mining was rapidly becoming the most important phase of the mining industry in Alaska. In 1951 the mines in the Territory produced 494,333 short tons of bituminous and subbituminous coal compared with 412,455 tons in 1950 and thus established an alltime record that surpassed the previous 1949 record of 433,533 tons by 14 percent. It was expected that the annual value of output of coal would soon reach if not surpass gold if the 1951 upward trend in production was maintained, particularly if the decrease in gold-mining activity continued. As in 1950, the greatest proportion of the output came from 3 mines operated by the Healy River Coal Corp. and Usibelli Coal Mine, Inc. in the Nenana (Healy) field and the Evan Jones Coal Co. in the Matanuska field.

The Evan Jones Coal Co., the largest producer in the Matanuska field and also the Territory, completed construction of a heavy-medium coal-separation plant at the Jonesville mine during the year and experimented with new types of underground mechanized equipment. Also in the Matanuska field, but in the western part, a relatively small quantity of coal was mined from the old Premier mine, formerly a major producer. The Duck Flat Co. operated the Duck Flat strip mine (formerly known as the Houston strip mine) on the Alaska Railroad north of Wasilla during the latter half of 1951 and supplied a limited quantity of coal to the military bases in the Anchorage area. The Buffalo mine, which had operated for a brief time in 1950, was inactive during 1951. The Bureau of Mines continued its diamond-drilling project in 1951 in the Wishbone Hill area of the Matanuska field to determine the minable reserves of bituminous coal. Operations for the season were concluded on October 1 owing to the unusually early and severe freeze.

Digitized by Google

Usibelli Coal Mines, Inc., the largest producer of coal from the Nenana field and second largest in the Territory in 1951, operated its strip mine on the Healy River at a steadily increasing rate from March through December, supplying coal under military contract for use in the Tanana Valley area. Mining in the main pit continued on the No. 1 bed, but in addition some coal was produced from a new strip operation on the south side of the Healy River. Adjacent to the Usibelli property, the Healy River Coal Corp. operated its Suntrana mine continuously throughout the year. Coal from this mine, the only underground operation in the field, supplied the rapidly expanding civilian demand in and around the city of Fairbanks and the Tanana Valley area. The company also produced some coal from a strip operation on the property. The Cripple Creek Coal Co. operated its strip mine on Cripple Creek during the spring of 1951 and fulfilled a contract with the Army. After several months of inactivity, additional ground was stripped in the late fall and some coal mined.

The Homer Coal Corp. operated its mine at the lower end of the Kenai Peninsula in the Homer field during the first half of 1951 to supply the limited demand of the local market; only a small quantity of coal was produced. The Alaska Native Service continued to operate its Mead River mine in the Point Barrow field to fill the limited local demand for coal in that part of the Northern Alaska region.

Because of the growing importance of coal in the economic pattern of Alaska, the history of the industry is briefly reviewed below. Coal in commercial quantity was produced first in Alaska from the Matanuska field (Doherty mine) in 1916 following completion of a branch of the Government-owned railroad to that area. It was not until 1920 that the present Evan Jones mine was opened and until 1922 that coal in commercial quantity was produced from the Nenana field. Until 1940 the Alaska Railroad was the principal consumer of coal largely from the Matanuska field, but subsequent ever-increasing demands for coal resulted from the establishment of military bases in the Anchorage and Fairbanks areas. By 1951 the military requirements exceeded all others, even though the consumption of coal for civilian use, particularly in power plants in the rapidly growing communities of Fairbanks and Anchorage, had increased markedly. The effects of these major events in the overall development of the Alaskan coal industry are shown graphically in figure 1.

Platinum Metals.—The Goodnews Bay Mining Co. continued to be the only producer of platinum in Alaska in 1951 and the only operator in the United States or its Territories that mined actively for platinum as a primary product. The company operated its electrically powered bucket-line dredge (with ninety-three 8-cubic-foot buckets) and a dragline (1¼-cubic-yard)-bulldozer-hydraulic combination on a bench of the Salmon River, Goodnews Bay district, Kuskokwim region, from May 2 to November 2. The recovery of crude platinum metals in 1951 was higher than in 1950; a small quantity of gold was obtained as a byproduct.

Pumice.—During 1951 a limited quantity of pumice was obtained by Stock & Grove from beach deposits at Geographic Bay off Shelikof Strait, Bristol Bay region. The material was shipped by barge to

Digitized by Google

Anchorage for subsequent use in the local manufacture of building blocks.

Sand and Gravel.—Production of sand and gravel in Alaska in 1951 amounted to 6,887,646 short tons. Producers were Alaska Concrete Products Co., Ketchikan; R. J. Sommers Construction Co., Juneau; the Alaska Road Commission; Bureau of Public Roads; Bureau of Reclamation; Naval Operating Base, Kodiak; and the Corps of Engineers, Department of the Army.

Tin.—Total production of tin in the Territory in 1951 was approximately 115 short tons of placer-tin concentrate containing 77 short tons (69 long tons) of tin. Although the output was 13 percent under that for 1950, the overall value increased 16 percent because of the higher average price per pound in 1951.

Tin mining in the Seward Peninsula region showed increasing activity in 1951. Although actual production from operating mines was less than in 1950, exploration and development projects, if carried through as planned, indicated that a much larger overall scale of operations could be expected in 1952. The U. S. Tin Corp. mined placer tin at its property on Lost River, Port Clarence district, during 1951; 40 short tons of tin-tungsten concentrate (containing 60.5 percent tin and 11 percent tungsten) recovered from 12,000 cubic yards of gravel washed was shipped but not sold. The company was developing a lode tin deposit on the property with the financial assistance of a Government operating loan, and expected to start producing tin concentrate from the new 100-ton mill early in 1952. The Northern Tin Co., Inc., recovered tin concentrate from its placer-tin operation on Buck Creek, Port Clarence district, using a dragline and jigs; the concentrate was shipped to the tin smelter at Texas City, Tex. Also in the Port Clarence district, but on Cape Creek near Tin City, the Zenda Gold Mining Co. started a program of placer tin exploration in 1951 with a $54,000 DMA 90-percent participation exploration loan. If results were to indicate sufficient reserves and favorable conditions, plans called for mining with a bucket-line dredge.

A small quantity of tin was recovered as a byproduct concentrate from placer-gold mining by several operators in the Yukon River Basin region. L. McGee, operating the property on Sullivan Creek and Tofty Gulch in the Hot Springs district formerly owned and worked by the Cleary Hill Mines Co., produced some concentrate. However, the material was not cleaned pending a more favorable price. In the same district Larson & Berg recovered a small quantity of tin from it's drift-mining operation on Woodchopper Creek; disposition of the concentrate was not reported. From Midnight Creek in the Ruby district John R. Campbell recovered a small quantity of tin concentrate left by previous operators who had mined the creek for gold; all of the material, which averaged 71 percent tin, was shipped to the tin smelter at Texas City, Tex.

Tungsten.—The Federal Government's tungsten-buying program, plus the strategic classification of the metal with possibility of obtaining a 75-percent Government participation exploration loan, resulted in an increased interest in tungsten in Alaska during 1951. Actual production was slight, being reported from only 3 properties. A small quantity of tungsten contained in tin-tungsten placer con-

Digitized by Google

centrate was shipped (but not sold) by the U. S. Tin Corp. from its property on Lost River, Port Clarence district, Seward Peninsula region. Rocky Mountain Mining Co. produced a small quantity of scheelite concentrate (60 percent WO_3) as a byproduct of placer-gold mining in the Nome district in 1951; the material was not shipped. Russell R. Schaefer recovered a minor quantity of scheelite as a by-product from a placer-gold operation on Forty-Seven Creek, tributary to Holitna River, Tuluksak-Aniak district, Kuskokwim region.

The Alaska Metals Mining Co. obtained a $44,558.50 DMA 75-percent Government participation exploration loan in 1951 and began exploration work on a lode-tungsten deposit (including the Stepovich and Colbert properties) on Gilmore Dome near Fairbanks. Plans included eventual construction of two 25-ton mills, one of which would be made available for custom milling.

The Riverside mine, a lead-tungsten property near Hyder, Southeastern Alaska region, a former producer of tungsten, did not operate in 1951.

Miscellaneous Minerals.—Data on production of stone are not available for publication. There was no recorded production of asbestos, bismuth, chromite, gemstones (jade), iron ore, mercury, nickel, or petroleum in Alaska in 1951.

The occurrence of bismuth on Charley Creek, 35 miles north of Nome, Seward Peninsula region, has been known for many years, but not until recently has any interest been shown in the deposit. In 1951 exploratory work was continued on the property by Native Bismuth, Inc., formed for the purpose of developing the deposit. The chromite deposit at Red Mountain, Kenai Peninsula region, was under investigation by a private operator, and negotiations were in progress relative to actively mining the property under a lease from the U. S. Vanadium Co. Although known for many years, the deposits of jade (nephrite) in the Cosmos Hills, Shungnak district, Northwestern Alaska region, had not been commercially exploited since the Arctic Circle Exploration Co. shipped a few tons to Fairbanks in 1946. Reportedly in 1951 the Imperial Jade Co., Kotzebue, Alaska, planned to mine Alaskan jade following a period of prospecting and exploration in the area. Past experience has indicated that most of the jade, found as float in form of boulders, cannot be classed as semiprecious stone, although some of the material is stated to be of gem quality. During 1951 interest was shown in the occurrences of magnetite in Southeastern Alaska as a source of iron ore for possible export to Japan, but no active exploitation resulted. Although no mercury was produced in Alaska in 1951 the DeCoursey Mountain Mining Co., a recent producer from deposits in the Kuskokwim region, sold its interests; the new owner reportedly planned resumption of operations in 1952. The Admiralty-Alaska Gold Mining Co. was granted a $108,000 90-percent Government participation DMA exploration loan in 1951 to explore for nickel and cobalt which is known to occur with copper in the Funter Bay mine, Admiralty Island district, Southeastern Alaska region.

The large exploration project conducted by the Navy in the Naval Petroleum Reserve No. 4, north of the Brooks Range, Northern Alaska region, continued throughout 1951. An extensive area of

Digitized by Google

gas-producing sands was discovered in 1951, and this in addition to other promising results obtained, demonstrated the value of the project which was to be continued full scale in 1952. Interest in the old Katalla oil field in the Yakataga district, Copper River region, was revived in 1951. The Northern Development Co. obtained control of a large acreage of potential oil land in the Katalla-Yakataga area. Reportedly the Deep Rock Oil Co. planned an oil-well drilling program in the field in 1952.

Arizona
Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By Paul Luff

GENERAL SUMMARY

DESPITE strikes for brief periods in 1951, Arizona's output of copper totaled 415,870 short tons, the largest in the State's history and 3 percent more than in 1950. On the other hand, gold production declined from 118,313 fine ounces in 1950 to 116,093 in 1951, a 2-percent loss; silver from 5,325, 441 fine ounces to 5,120,985, a 4-percent loss; lead from 26,383 short tons to 17,394, a 34-percent loss; and zinc from 60,480 short tons to 52,999, a 12-percent loss. Most of the gold and silver produced in Arizona is a byproduct of copper and zinc-lead ores; in 1951 these two classes of ore yielded 105,703 ounces of gold and 4,231,061 ounces of silver compared with 103,311 and 4,459,176 ounces, respectively, in 1950. However, the loss in gold from lead ore and zinc-lead ore in 1951 more than offset the increase from copper ore. The decreased lead and zinc production resulted mainly from a decline in output of zinc-lead ore from the Copper Queen mine at Bisbee, where zinc-lead ore reserves are nearly depleted. The State remained the largest producer of copper in the United States; ranked fourth in silver, fifth in gold and zinc, and sixth in lead; and again ranked first in total value of the five metals.

The total value of the five metals was $235,289,045 in 1951, the highest in any year in the State's history and a 17-percent gain over the $201,033,694 in 1950. Gold production amounted to $4,063,255—nearly 2 percent of the State total value; silver, $4,634,750—2 percent; copper, $201,281,080—over 85 percent; lead, $6,018,324—over 2 percent; and zinc, $19,291,636—8 percent. The value of the metals recovered from copper ore was $201,685,281 in 1951 ($169,717,981 in 1950) or 86 percent of the State total, and that recovered from zinc-lead ore was $18,577,376 ($23,035,993 in 1950) or 8 percent of the total. About 92 percent of the gold production and 78 percent of the silver came from 6 districts—Ajo, Big Bug, Copper Mountain (Morenci), Pioneer (Superior), Verde (Jerome), and Warren (Bisbee); 99 percent of the copper came from 8 districts—Ajo, Copper Mountain (Morenci), Eureka (Bagdad), Globe-Miami, Mineral Creek (Ray), Pioneer (Superior), Verde (Jerome), and Warren (Bisbee); 90 percent of the lead came from 6 districts—Aravaipa, Big Bug, Harshaw, Old Hat, Pima, and Warren (Bisbee); and 96 percent of the zinc came from 10 districts—Aravaipa, Big Bug, Cochise (Dragoon), Eureka (Bagdad), Harshaw, Old Hat, Pima, Pioneer (Superior), Verde (Jerome), and Warren (Bisbee).

Outstanding features of Arizona's mining activities in 1951 were the record production of copper ore, especially from open pits; of

Digitized by Google

zinc-copper ore from the Cedar Valley, Cochise, Eureka, Pioneer, and Verde districts; of copper in the Mineral Creek district; and of zinc in the Verde district.

Arizona's producing mines declined in number from 333 (including 24 placers) in 1950 to 283 (including 18 placers) in 1951.

All tonnage figures reported herein are short tons and "dry weight"; that is, they do not include moisture. The value of production has been calculated at the prices shown in table 1.

TABLE 1.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] (per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

[1] Price under authority o fGold Reserve Act of Jan. 31, 1934.
[2] Treasury buying price for newly mined silver July 1, 1946, to date—$0.9050505 ($0.905 used in 1947 for calculating purposes).
[3] Yearly average weighted price of all grades of primary metal sold by producers. Price in 1947 includes bonus payments by Office of Metals Reserve for overquota production.

The average prices of copper, lead, and zinc all increased in 1951—copper to 24.2 cents a pound, lead to 17.3 cents, and zinc to 18.2 cents. The Treasury price of gold remained at $35 a fine ounce and of silver at $0.905+. On October 2 the price of lead rose from 17 cents a pound to 19 cents and zinc from 17.5 cents a pound to 19.5 cents.

TABLE 2.—Mine production of gold, silver, copper, lead, and zinc in Arizona in 1951, by months, in terms of recoverable metal [1]

Month	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)
January	10,832	443,198	37,065	1,520	4,295
February	9,057	409,800	32,750	1,485	4,150
March	10,822	475,000	37,960	1,655	4,780
April	10,976	474,000	38,170	1,490	4,275
May	11,038	487,200	37,770	1,650	4,825
June	9,787	422,000	31,890	1,475	4,145
July	9,272	401,274	33,510	1,410	4,105
August	8,780	375,340	31,165	1,440	4,910
September	8,072	378,143	30,460	1,275	3,920
October	9,147	421,345	36,310	1,335	4,975
November	9,080	410,342	33,760	1,320	4,335
December	9,230	423,343	35,060	1,339	4,284
Total	116,093	5,120,985	415,870	17,394	52,999

[1] Mine production comprises ore, gravel, or other mineral material sold or treated and metal recovered as natural gold or as bullion from cyanidation or amalgamation and the estimated recoverable metal (or gross metal as indicated) contained in concentrates, ores, tailings, and other mineral materials shipped directly to smelters or sold to ore buyers within the year.

Gold.—Arizona's gold production declined to 116,093 fine ounces in 1951, a loss of 2,220 ounces (2 percent) from 1950. A substantial increase in gold production from the Copper Queen mine of the Phelps Dodge Corp. prevented a greater loss. Most of the gold, as well as silver, produced in the State is a byproduct of copper ore and zinc-lead ore; in 1951 copper ore yielded 83,521 ounces of gold (72 percent of the total), an increase of 3,954 ounces over 1950, and zinc-lead ore 22,182 ounces (19 percent of the total), a decrease of 1,562 ounces. However, a decrease of 4,388 ounces of gold from lead ore and 1,823 ounces from gold, gold-silver, and silver ores more than offset the increase from copper ore. Gold from placers increased from 142 ounces to 156. The New Cornelia copper mine of the Phelps Dodge Corp. in Pima County continued to be the leading gold producer in the State; it was followed by the Copper Queen mine of the Phelps Dodge Corp. in Cochise County, the Iron King mine in Yavapai County, the Magma mine in Pinal County, the Morenci mine of the Phelps Dodge Corp. in Greenlee County, and the United Verde mine of the same corporation in Yavapai County; these six properties produced 92 percent of the total gold.

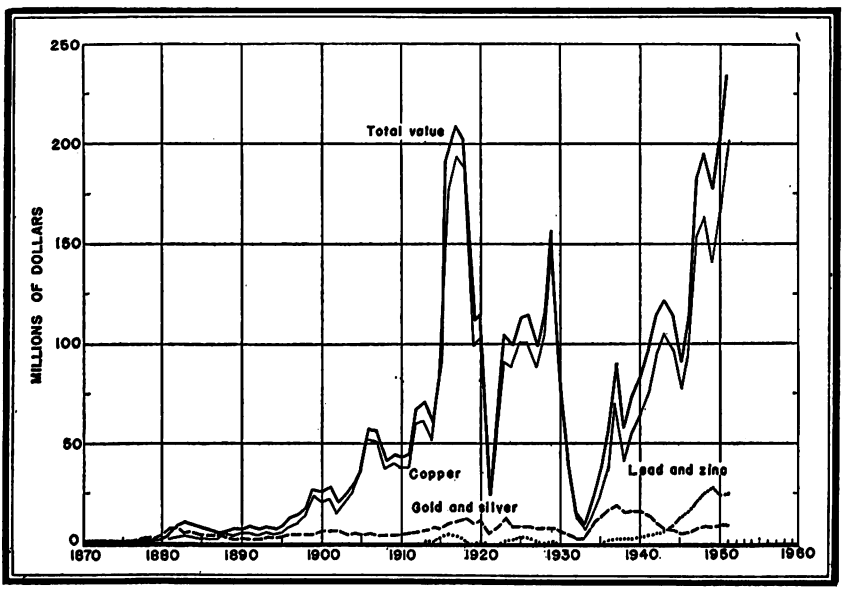

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc in Arizona, 1870–1951.

Silver.—A decline in the quantity of silver recovered from zinc-lead ore caused Arizona's silver production to decrease to 5,120,985 fine ounces in 1951—204,456 ounces (4 percent) less than in 1950. Copper ore yielded 3,087,865 ounces (60 percent of the State total), an increase of 234,266 ounces (8 percent) over 1950; and zinc-lead ore yielded 1,143,196 ounces (22 percent of the total), a decrease of 462,381 ounces (29 percent). Most of the remainder of the silver came from zinc-copper ore (602,083 ounces) and from silver ore (242,850 ounces). The Phelps Dodge Corp., with a slightly lower

Digitized by Google

output than in 1950, continued to be the chief silver producer in Arizona; its 4 properties (Copper Queen, Morenci, New Cornelia, and United Verde) produced 54 percent of the State total. Other large silver producers were Iron King, Magma, Ash Peak, Ray (Kennecott), Flux, and San Xavier (Eagle-Picher) properties.

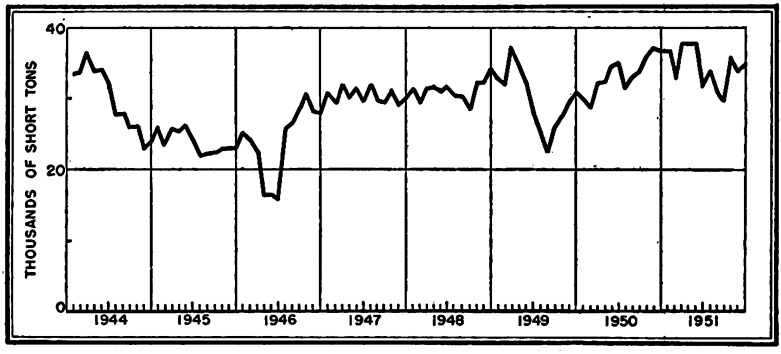

FIGURE 2.—Mine production of copper in Arizona, 1944–51, by months, in terms of recoverable metal.

Copper.—Arizona's output of recoverable copper was 415,870 short tons in 1951, the largest ever recorded and 12,569 tons (3 percent) more than in 1950. Substantial increases in output from the Globe-Miami, Mineral Creek, and Warren districts more than offset large decreases from the Copper Mountain, Eureka, Pioneer, and Verde districts. The Copper Mountain district, with an output of 143,921 tons, remained the leading copper-producing district in the State, although its output declined 7 percent, it was followed by the Globe-Miami district with 90,225 tons, Ajo with 63,093, Mineral Creek with 50,580, Warren with 27,271, Pioneer with 17,662, Verde with 9,742, and Eureka with 9,087. Copper production at the Ray property of the Kennecott Copper Corp. increased 14,189 tons (39 percent), and that at the Copper Queen mine of the Phelps Dodge Corp. 13,926 tons (104 percent). There were also substantial increases at the Castle Dome and Miami properties. The total copper yield of 809,781,829 pounds was obtained as follows: 38,545,214 tons of copper ore treated by concentration, 82 percent; 3,696,413 tons of copper ore leached and 24,331 tons of cement copper (from mine-water precipitates and underground leaching operations), 12 percent; and 542,761 tons of copper ore shipped crude to smelters, 6 percent. The Morenci mine (Phelps Dodge) was again the largest copper producer in Arizona, followed in order by the New Cornelia (Phelps Dodge), Ray, Inspiration Copper Queen, Miami, Castle Dome, Magma, United Verde (Phelps Dodge), and Bagdad properties. These 10 properties produced 99 percent of the State total.

Lead and Zinc.—Arizona's production of recoverable lead and zinc was much less than in 1950, lead dropped to 17,394 short tons—a decrease of 8,989—and zinc to 52,999 tons—a decrease of 7,481. These decreases resulted mainly from a decline in ouput of zinc-lead ore from the Copper Queen mine at Bisbee, where zinc-lead ore reserves are nearly depleted. Substantial increases in production from the

Digitized by Google

Magma, United Verde, Republic & Mammoth, and Old Dick properties prevented a greater loss in the State zinc output. The St. Anthony property at Tiger in Pinal County was the leading lead producer in 1951 followed by the Iron King mine at Humboldt, San Xavier mine near Sahuarita, Flux group near Patagonia, Copper Queen mine at Bisbee, and Aravaipa group near Klondyke. The leading zinc producer in 1951 was the United Verde mine of the Phelps Dodge Corp., followed by the Iron King, Magma, San Xavier, Copper Queen, Flux, St. Anthony, Republic & Mammoth, Old Dick, and Aravaipa properties. Large lead- and zinc-producing districts in 1951 were the Big Bug in Yavapai County, Old Hat in Pinal County, Pima in Pima County, Harshaw in Santa Cruz County, Warren in Cochise County, and Aravaipa in Graham County. Additional large zinc-producing districts were the Verde in Yavapai County, Pioneer in Pinal County, Cochise in Cochise County, and Eureka in Yavapai County. About 92 percent of the lead and 55 percent of the zinc came from zinc-lead ore; 5 percent of the lead came from lead ore, and most of the remainder of the lead came from zinc-copper ore and zinc-lead-copper ore; 42 percent of the zinc came from zinc-copper ore and most of the remainder from zinc ore and zinc-lead-copper ore.

TABLE 5.—Mine production of gold, silver, copper, lead, and zinc in Arizona in 1951, by counties, in terms of recoverable metal

County	Mines producing		Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer	Fine ounces	Value	Fine ounces	Value
Cochise	27	----------	25,555	$894,425	1,332,655	$1,206,120

MINING AND METALLURGICAL INDUSTRY

Stimulated by high prices of copper and zinc, the output of copper ore and zinc-copper ore in Arizona in 1951 reached record peaks. The output of copper ore increased to 42,784,388 tons, a gain of 1,027,115 tons (2 percent) over 1950, and zinc-copper ore increased to 433,256 tons, a gain of 184,865 tons (74 percent). On the other hand, the output of zinc-lead ore declined to 503,300 tons, a loss of 114,247 tons (19 percent), and that of gold ore, silver ore, gold-silver ore, and lead ore also declined. The demand for copper was strong throughout the year, and during the first half of the year (with no interruptions by strikes) mining of copper ore was at a higher rate than at any time in the State's history; however, strikes interfered with operations a few days during the last quarter. Of the total ore, 42,744,404 tons (nearly 98 percent) was copper ore mined in the Ajo, Copper Mountain, Eureka, Globe-Miami, Mineral Creek, Pioneer, Verde, and Warren districts. The remainder comprised 494,949 tons of zinc-lead ore mined in the Aravaipa, Big Bug, Harshaw, Old Hat, Pima, and Warren districts; 432,364 tons of zinc-copper ore mined in the Cedar Valley, Cochise, Eureka, Pioneer, and Verde districts; and 66,540 tons of miscellaneous ores from districts throughout the State. Mining operations at 6 open pits—Ajo, Bagdad, Inspiration, Miami (Castle Dome), Morenci, and Ray—produced 34,839,237 tons of copper ore averaging 1.003 percent copper, compared with 33,358,059 tons of ore in 1950, averaging 1.033 percent copper. More copper ore was mined from open pits in 1951 than in any other year.

Steps were taken by the Federal Government in 1951 to stimulate production of critical and strategic minerals by assisting in the financing of exploration projects. Seven exploration projects were approved for Arizona, with the Government providing $314,275.60 of the cost and private industry $215,180.40. Minerals being sought include copper, lead, zinc, and asbestos. The Government's contribution will be repaid, without interest, through a royalty on net returns if ore is discovered or delineated during the exploration projects and the ore is mined within 10 years of the date of the contract.

Of the 43,820,353 tons of ore, old tailings, etc., mined and treated in 1951 in Arizona, 39,491,121 tons (90 percent) was treated at 36 milling plants, 3,696,413 tons (nearly 9 percent) at 1 straight-leaching (copper) plant, and 632,819 tons (over 1 percent) was shipped crude to smelters.

Crude ore treated at milling plants comprised chiefly 38,545,214 tons of copper ore, averaging 1.042 percent copper and carrying minor quantities of gold and silver per ton; 497,738 tons of zinc-lead ore, averaging 0.06 ounce of gold and 2.72 ounces of silver to the ton, 0.38 percent copper, 3.58 percent lead, and 7.53 percent zinc; and 433,256 tons of zinc-copper ore, averaging 0.04 ounce of gold and 2.00 ounces of silver to the ton, 2.57 percent copper, 0.40 percent lead, and 7.49 percent zinc. Copper ore from the Miami property was treated by a combination of leaching and concentration, and copper ore from the Inspiration mine was treated both by straight leaching and by leaching and concentration. The most important mills that operated nearly all year were the copper-concentration plants at Morenci (45,000 tons a day), Ajo (25,000 tons), Miami (18,000 tons), Inspiration (18,000 tons), Castle Dome (10,000 tons), Hayden (10,000 tons),

Digitized by Google

Bagdad (4,000 tons), Clarkdale (2,100 tons), and Superior (1,500 tons); the copper-leaching plants at Inspiration (9,000 tons) and Miami (3,000 tons); and the zinc-lead concentration mills at Bisbee (Copper Queen 900 tons), Humboldt (Iron King 670 tons), Sahuarita (Eagle-Picher 500 tons), Tiger (St. Anthony, 500 tons), Patagonia (Trench 200 tons), and Klondyke (Athletic 100 tons). The concentrators at Clarkdale and Superior, as well as those near Bagdad, Dragoon, and Yucca, also treated zinc-copper ore. Six copper smelters in Arizona—Phelps Dodge Corp. at Ajo, Douglas, and Morenci, International Smelting & Refining Co. at Miami, American Smelting & Refining Co. at Hayden, and Magma Copper Co. at Superior—operated nearly all year. Most of the copper concentrates produced at mills in Arizona were treated at smelters in the State. However, all the lead concentrates produced were shipped to the smelter at El Paso, Tex., and all the zinc concentrates were shipped to smelters at Amarillo, Corpus Christi, and Dumas, Tex.; Bartlesville and Henryetta, Okla.; St. Louis, Mo.; Anaconda and Great Falls, Mont.; and Canon City, Colo.

ORE CLASSIFICATION

Definitions used in ore classification are given in the Gold and Silver chapter of this volume.

TABLE 6.—Mine production of gold, silver, copper, lead, and zinc in Arizona in 1951, by class of ore or other source material, in terms of recoverable metal

Source	Number of mines[1]	Material sold or treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore:							
Dry gold	32	3,418	1,085	3,296	24,282	2,758	1,133
Dry gold-silver	4	186	68	2,064	1,409	1,350	----
Dry silver	27	27,567	780	242,850	38,602	18,407	----
Total	63	31,171	1,933	248,210	64,293	22,515	1,133
Copper	89	42,784,388	83,521	3,087,865	775,609,514	975	----
Lead	73	5,809	297	20,839	22,911	1,603,484	74,988
Lead-copper	2	2	----	9	132	1,100	----
Zinc	9	8,859	15	5,705	73,482	35,802	2,390,756
Zinc-copper	11	433,256	7,507	602,083	18,793,528	966,278	44,769,830
Zinc-lead	40	503,300	22,182	1,143,196	2,537,980	31,970,799	58,358,337
Zinc-lead-copper	4	2,643	----	6,640	137,905	144,326	397,400
Total	211	43,738,257	113,522	4,866,337	797,175,452	34,722,764	105,991,311
Other "lode" material:							
Old tailings, etc.[2]	10	50,925	482	6,427	327,940	42,721	5,556
Copper precipitates	6	----	----	----	34,172,315	----	----
Total	16	50,925	482	6,427	34,500,255	42,721	5,556
Total "lode" material	265	43,820,353	115,937	5,120,974	831,740,000	34,788,000	105,998,000
Gravel (placer operations)	18	----	156	11	----	----	----
Total, all sources	283	43,820,353	116,093	5,120,985	831,740,000	34,788,000	105,998,000

[1] Detail will not necessarily add to totals because some mines produce more than one class of ore.
[2] Old tailings: Gold, 56 tons; gold-silver, 43,980 tons; copper, 6,682 tons; lead, 2 tons. Smelter cleanings: Copper, 41 tons; lead, 152 tons. Mill cleanings: Gold, 12 tons.

REVIEW BY COUNTIES

COCHISE

In 1951 Cochise County ranked first in silver output in Arizona, third in gold and zinc, and fifth in copper and lead. The Copper Queen mine of the Phelps Dodge Corp. at Bisbee in the Warren district was by far the most important producer in the county, the corporation reporting that the mine produced 490,184 tons of copper ore and 40,426 of zinc-lead-silver ore in 1951 compared with 218,404 and 153,730 tons, respectively, in 1950. In addition, 311 tons of copper precipitates were produced. The zinc-lead-silver ore and 119,454 tons of copper ore were treated in the corporation 900-ton flotation mill at Bisbee; the remainder of the copper ore and the copper precipitates were shipped direct to the corporation smelter at Douglas.

According to the corporation annual report for 1951, the Copper Queen mine produced 55,837,413 net pounds of copper, 2,530,056 of lead, and 7,432,219 of zinc, compared with 21,203,333, 11,606,250, and 33,423,374 pounds, respectively, in 1950. The changeover during the year from mining important quantities of zinc-lead-silver ore to mining almost exclusively copper ore, was completed. This changeover began in 1950 as a result of virtual exhaustion of zinc-lead-silver deposits.

During 1951 the corporation began developing an open pit at the Bisbee East ore body (known as the Lavender pit). The ore body contains an estimated 41,000,000 tons of milling ore averaging 1.14 percent copper and 31,000,000 tons of leaching material averaging 0.42 percent copper.

Other county production included 64,654 tons of zinc-copper ore from the Republic and Mammoth mines of the Coronado Copper & Zinc Co. near Dragoon in the Cochise district. The company operated its 200-ton flotation mill all year and produced 4,295 tons of copper concentrate and 6,228 tons of zinc concentrate. The Abril group in the Turquoise district was operated under lease by Sherwood B. Owens, who shipped 5,427 tons of zinc ore to a custom mill in Deming, N. Mex. Zinc ore (295 tons) was also produced from the San Juan (Gordon) mine; zinc-copper ore (320 tons), copper ore (86 tons), and zinc-lead ore (14 tons) from the Shannon mine; and zinc-lead ore (102 tons) from the Defiance mine. Output from the California district was largely 525 tons of zinc-lead ore shipped from the Doran Sun Set waste dumps and 150 tons of lead ore from the Hilltop and Leadville mines. Copper ore (22 tons) was produced from the Tout group in the Dos Cabezas and Tevis district. Output from the Swisshelm district was 1,746 tons of lead ore from the Chance and Scribner mines. In the Tombstone district, production was mainly 665 tons of silver ore from the Tombstone group, 280 tons of zinc-lead ore from the Mary Jo group, and 87 tons of lead ore from the Gallagher-Bradshaw group.

GILA

Gila County, with a production of 182,114,000 net pounds of copper in 1951 (170,740,700 in 1950), continued to rank second among the copper-producing areas in Arizona. About 99 percent of the output came from the Globe-Miami district, where there are three large pro-

ducers—Castle Dome, Inspiration, and Miami. The Inspiration property, with a yield of 78,249,439 net pounds of copper in 1951, remained the leading copper producer in the county and ranked fourth in the State. The Inspiration Consolidated Copper Co. reported that 3,696,413 tons of ore, averaging 0.987 percent copper, was treated in 1951 by acid ferric sulfate in the main leaching plant; 315,265 tons of slimes, removed from ore at the main leaching plant, was treated by flotation, and 7,932 tons of copper ore and 8,181 tons of cement copper were sent direct to the smelter at Miami. Ore production was from both underground and open pit: 2,043,125 tons was mined from underground and 1,983,297 tons from the open pit.

The Miami mine of the Miami Copper Co. and the Castle Dome Copper Co., Inc. (a wholly-owned subsidiary of the Miami Copper Co.) produced 101,668,368 net pounds of copper in 1951 (51,955,582 pounds from the Miami and 49,712,786 pounds from the Castle Dome). According to the annual report of the Miami Copper Co., copper was produced at the Miami mine by under ground mining followed by flotation and by acid leaching of material overlying the mined-out areas. The company 18,000-ton concentrator treated 3,812,045 tons of ore averaging 0.727 percent copper and containing small quantities of gold and silver; re-treatment of copper concentrate recovered 589,996 pounds of molybdenum. Ore reserves, as of January 1, 1952, were estimated to be 12,000,000 tons. The Castle Dome open pit and 10,000-ton concentrator were operated continuously in 1951; 3,864,250 tons of ore averaging 0.758 percent copper and containing small quantities of gold and silver was treated. As of January 1, 1952, ore reserves were estimated to be 7,033,468 tons. According to the same annual report, operations at the Copper Cities Mining Co. (wholly owned subsidiary of Miami Copper Co.) property had advanced sufficiently by June 1951 to allow the beginning of stripping. The in-place ore reserves, after establishment of final pit limits, are estimated at 33,000,000 tons.

The remainder of the Globe-Miami district output was largely 557 tons of copper ore from the Blue Bird, Copper Hill, Four Bagger, Free America, High Line, and Pontiac properties.

Output in the Banner district was chiefly 30,305 tons of high-lime fluxing ore, containing an average of 2.696 percent copper, and 6,682 tons of old siliceous copper tailings shipped from the Christmas property to the copper smelter at Hayden. Norman C. Grissom operated the "79" mine and shipped 275 tons of lead ore; 100 tons of copper ore was produced from the Chilito claim. In the Dripping Springs district, C. F. Moores worked the C–B claim and shipped 138 tons of zinc-lead ore. Output in the Summit district was 37 tons of copper ore from the Yan claim.

GRAHAM

Output in Graham County was mainly zinc-lead ore from the Aravaipa district, where the principal producer was the Aravaipa group of mines operated by the Athletic Mining Co. The company reported that 26,148 tons of zinc-lead ore was treated in its 100-ton flotation mill and that 2,195 tons of similar ore was shipped direct to the lead smelter at El Paso, Tex. Other producers of zinc-lead ore were the Sein Fein mine (1,868 tons), Santa Teresa mine (458 tons),

Digitized by Google

and Ben Hur group (107 tons). The Abe Reed mine produced 121 tons of lead ore.

GREENLEE

Greenlee County, with a production of 287,842,000 net pounds of copper in 1951 (309,378,100 in 1950), continued to be the chief copper-producing area in Arizona, as the Morenci mine of the Phelps Dodge Corp. at Morenci in the Copper Mountain district remained the outstanding producer of copper in the State, although its output was 6 percent less than in 1950. The corporation reported that 15,466,625 tons of copper ore from the Morenci mine was treated in the 45,000-ton concentrator in 1951 and that 525,261 tons of copper concentrate, 71,299 tons of crude copper ore, and 5,576 tons of copper precipitates were shipped direct to the Morenci smelter. In addition, 487 tons of molybdenum concentrate was produced, and the mine was also an important producer of gold and silver.

Other Copper Mountain district production was 57 tons of gold-silver ore from the Bell group and 6 tons of copper ore from the X. I. V. claim. In the Ash Peak district, the Ash Peak Lease continued to operate the Ash Peak mine near Duncan and shipped 19,309 tons of fluxing ore, averaging 0.036 ounce of gold and 10.017 ounces of silver to the ton and 80 percent silica.

MARICOPA

The principal output in Maricopa County was 100 tons of gold ore from the Charlotte mine in the White Butte district. Gold ore (36 tons) was produced also from the Altuda mine in the Estrella Mountain district, and copper-silver ore (33 tons) from the Red Rover mine in the Cave Creek and Camp Creek district.

MOHAVE

The most important operation in Mohave County was the mining of zinc-copper ore at the Antler and Copper World mines near Yucca in the Cedar Valley district. The Antler mine, operated all year by the Yucca Mining & Milling Co., produced 17,039 tons of ore that contained 120 ounces of gold, 12,500 ounces of silver, 800,000 pounds of copper, 240,000 pounds of lead, and 1,500,000 pounds of zinc. The Mountain States Metals Co. took over operation of the Copper World mine early in 1951, constructed a 75-ton flotation mill, and began milling zinc-copper ore in May; total ore milled was 4,500 tons. Other county production included 107 tons of copper ore from the Cox Ross and Grand Gulch properties in the Bentley (Grand Wash Cliffs) district; 59 tons of lead ore from the McCracken mine in the Owens district; and 666 tons of zinc-lead ore from the Banner, Champion, DeLa-Fountaine, and Fountain Head mines and 550 tons of lead ore from the Cupel, DeLaFountaine, Little Tennessee, New London, Western Union, and Wrigley properties in the Wallapai district.

PIMA

In 1951 Pima County ranked first in gold output in Arizona, third in lead, fourth in copper and zinc, and fifth in silver. Most of the output was copper ore from the New Cornelia mine of the Phelps Dodge

Corp. in the Ajo district and zinc-lead ore from the San Xavier property of The Eagle-Picher Co. (formerly Eagle-Picher Mining & Smelting Co.) in the Pima district. According to the annual report of the Phelps Dodge Corp., the open pit at the New Cornelia mine produced 9,164,309 tons of copper ore in 1951 compared with 8,790,024 in 1950. However, smelter production of copper from concentrates treated declined from 131,717,340 pounds to 129,553,788. In addition, 43,980 tons of old siliceous copper tailings was shipped to the Ajo smelter for fluxing purposes.

The San Xavier group near Sahuarita in the Pima district, one of the most important producers of zinc-lead ore in Arizona, was operated 11½ months. The Eagle-Picher Co. reported that the mine produced 71,182 tons of zinc-lead ore in 1951 compared with 67,456 tons in 1950. Other production in the Pima district included 120 tons of copper ore from the Vulcan mine, 74 tons of lead ore from the Old Powers and Red Hill properties, and 46 tons of zinc-lead ore from the Tit-for-Tat claim.

In the Cababi district the output was mainly 138 tons of copper ore from the Emperor & Duchess mine and 90 tons of gold-silver ore from the Cunquian mine. The S R K mine near Consair in the Coyote district produced 30 tons of copper ore. Phil Snyder worked the Conglomerate mine in the Greaterville district in 1951 and shipped 74 tons of lead ore. Output from the Growler district was 198 tons of copper ore produced from the Jeff Milton property. Lessees operated several mines in the Helvetia district and shipped 7,907 tons of copper ore (3,398 tons was produced from the King in Exile mine, 1,244 tons from the Old Dick mine, 1,212 tons from the Elgin mine, 1,095 tons from the Peach mine, 623 tons from the Mineral Hill mine, 204 tons from the Bulldozer mine, 74 tons from the Forbes claim, 36 tons from the South End claim, and 21 tons from the Daylight claim). Output from the Old Hat district in Pima County was 83 tons of copper ore from the Leatherwood mine and 12 tons of lead ore and 7 tons of zinc-lead ore from the Bluff claim.

PINAL

In 1951 Pinal County ranked first in lead output in Arizona, second in zinc, third in silver and copper, and fourth in gold. The most important operations were copper mining in the Mineral Creek district, copper mining and zinc-copper mining in the Pioneer district, and zinc-lead mining in the Old Hat district. Owing to extensive operations by the Kennecott Copper Corp. at the open pit of the Ray property, the mine made a record output of copper ore. The corporation reported that 3,061,636 tons of ore was mined from the open pit and 1,163,728 tons from underground—a total of 4,225,364 tons compared with 3,063,703 tons in 1950. The milling ore (4,213,154 tons), averaging 1.392 percent copper, was coarse-crushed at the mine, and the resulting product hauled by rail 26 miles to the corporation flotation mill at Hayden. In addition, 12,210 tons of crude smelting ore and 4,114 tons of copper precipitates were shipped to smelters in Arizona and New Mexico.

The remainder of the district output was 5,291 tons of siliceous ore, averaging 3.186 percent copper, produced from the Copper Butte open pit and 168 tons of oxide lead ore from the Ray Silver-Lead and Richard Arlyn properties.

Digitized by Google

In the Pioneer district, the Magma mine of the Magma Copper Co., one of the most important producers of gold, silver, copper, and zinc in Arizona, produced 307,590 tons of copper ore, 118,157 tons of zinc-copper ore, and 5,443 tons of siliceous silver fluxing ore in 1951, compared with 371,846, 50,527, and 6,342 tons, respectively, in 1950.

According to the company annual report for 1951, the Magma mine, mill, and smelter operated 6 days a week throughout the year, and labor supply was sufficient to maintain production at full capacity. The net metal produced from Magma crude smelting ore and concentrates comprised 10,962 ounces of gold, 491,223 ounces of silver, and 36,934,477 pounds of copper; 12,628 tons of zinc concentrate was produced, averaging 51.133 percent zinc. About 1 year's production of zinc-copper ore remained at the end of the year.

The rest of the district output was mainly 742 tons of gold-copper ore from the Lake Superior & Arizona group and 75 tons of silver ore from the Reymert Extension, Silver King, and Whetrock properties.

Output of zinc-lead ore in the Old Hat district declined from 115,357 tons in 1950 to 102,775 tons in 1951. Nevertheless, the district remained one of the most important producers of zinc and lead in Arizona. All but 89 tons of the zinc-lead ore came from the Mammoth-Collins group of the St. Anthony Mining & Development Co., Ltd. The company reported that 102,686 tons of ore, averaging 0.008 ounce of gold and 1.08 ounces of silver to the ton, 0.46 percent copper, 4.87 percent lead, and 5.30 percent zinc, were treated in its 500-ton gravity-flotation mill in 1951. The remainder of the district output was largely 482 tons of lead ore and 89 tons of zinc-lead ore from the Stove Lid claim.

No ore was produced in 1951 from the San Manuel property of the San Manuel Copper Corp. (wholly owned subsidiary of Magma Copper Co.) south of Tiger in the Old Hat district, but additional diamond drilling and churn drilling during the year increased proved ore reserves to a total of 479,500,000 tons averaging 0.77 percent copper.

Siliceous silver fluxing ore continued to be the principal output in the Casa Grande district; 1,813 tons of this ore was shipped from the Silver Reef mine. In the Dripping Springs (Troy) district, 38 tons of copper ore was produced from the Rattler group and 37 tons of zinc-lead ore from the Barton or 91 group. Output of the Goldfields district was virtually all gold ore (1,965 tons) produced from the old Mammoth mine near Apache Junction. The United Arizona Mines, Inc., worked the Silver Bell mine in the Martinez Canyon district, treated 330 tons of lead ore by concentration, and shipped 243 tons of similar ore direct to a smelter. Output of the Mineral Hill district comprised mainly 123 tons of zinc-lead ore from the Rock Cliff-Silver King group, 60 tons of gold ore from the Sunset and West mines, 52 tons of silver ore from the Silver Bar and Woodpecker claims, and 38 tons of lead ore from the Grey Eagle claim. The American mine in the Summit district produced 34 tons of copper ore. Lessees worked the old Reward mine in the Vekol district and shipped 389 tons of zinc ore to a custom mill in New Mexico and 134 tons of copper ore to smelters in Arizona and Texas.

SANTA CRUZ

Zinc-lead-silver ore from the Flux mine of the American Smelting & Refining Co. near Patagonia in the Harshaw district was the most

Digitized by Google

important output in Santa Cruz County. The mine and the company 200-ton flotation mill were operated continuously throughout the year; output of zinc-lead-silver ore increased from 46,365 tons in 1950 to 46,966 in 1951. The mill also treated custom ores totaling 8,004 tons.

Seventeen mines in the Patagonia district produced 7,897 tons of ore in 1951 containing 39,246 ounces of silver, 258,301 pounds of copper, 556,979 pounds of lead, and 1,417,183 pounds of zinc. The bulk of the output was the 4,496 tons of zinc-lead ore, 2,373 tons of zinc-lead-copper ore, 425 tons of zinc ore, and 122 tons of zinc-copper ore produced by lessees from 11 claims of the Duquesne group; all of the ore was treated in the flotation mill of the American Smelting & Refining Co. near Patagonia. Other district production was largely 270 tons of zinc-lead-copper ore from the Pride of the West mine and 138 tons of lead ore from the Mowry and Mudbank groups.

The Tyndall district produced 587 tons of ore—437 tons was lead smelting ore from the Bull Springs, Glove, and Wilkins properties and 150 tons zinc-lead ore and gold-silver ore from the Bull Springs and San Ramon groups.

YAVAPAI

In 1951 Yavapai County ranked first in zinc output in Arizona second in gold, silver, and lead, and sixth in copper. Most of the output was copper ore from the Bagdad mine in the Eureka district, zinc-copper ore and copper ore from the United Verde mine in the Verde district, and zinc-lead-iron ore from the Iron King mine in the Big Bug district.

In the Big Bug district the Iron King mine of the Shattuck Denn Mining Corp. at Humboldt was virtually the only producer. The corporation reported that the mine produced 202,581 tons of ore averaging 0.134 ounce of gold and 3.78 ounces of silver to the ton, 0.16 percent copper, 2.36 percent lead, 6.44 percent zinc, and 16.70 percent iron. The mine ore and 1,143 tons of custom ores were treated in the company 670-ton flotation mill.

Six mines in the Eureka district produced 1,250,207 tons of ore in 1951 containing 293 ounces of gold, 86,358 ounces of silver, 21,582,268 pounds of copper, 234,297 pounds of lead, and 6,472,245 pounds of zinc. The most important output was copper ore produced from the open pit at the Bagdad mine by the Bagdad Copper Corp. The corporation reported that 1,231,613 tons of ore, averaging 0.836 percent copper, was treated in its 4,000-ton flotation mill in 1951. Other district production was largely 15,528 tons of zinc-copper ore from the Old Dick mine, 2,186 tons of zinc ore from the Copper King mine, and 537 tons of zinc-lead ore from the Hillside and Mountain Springs properties.

In 1951 the Verde district produced 212,391 tons of zinc-copper ore, 87,338 tons of copper ore, and 159 tons of copper precipitates compared with 161,281, 199,803, and 141 tons respectively in 1950. All the output came from the United Verde mine of the Phelps Dodge Corp., where production of zinc-copper ore was 32 percent more than in 1950 but production of copper ore was 56 percent less. All the ore was treated in the corporation 2,100-ton flotation mill. The property ranked first in zinc production in Arizona in 1951, sixth in gold and silver, and ninth in copper.

Digitized by Google

The remainder of Yavapai County production was largely 1,074 tons of zinc-lead ore from the Cash and Combination mines, 227 tons of gold-lead ore from the Bodie mine, and 59 tons of zinc ore from the Evergreen claim in the Hassayampa district, 450 tons of zinc-copper ore from the French Lilly group near Cleator in the Black Canyon district; 313 tons of copper ore from the Abe Lincoln, Monte Cristo, and Unida mines in the Black Rock district; 308 tons of gold ore from the Gladiator mine at Crown King in the Pine Grove district; 108 tons of gold ore from the Dutchman, M. B., Monica, Octave, and Red Bird properties in the Weaver district; 66 tons of copper ore from the Golden Gate mine in the Blue Tank district; and 56 tons of zinc-lead ore from the U. S. Navy mine in the Copper Basin district.

YUMA

The principal output in Yuma County in 1951 was 702 tons of gold ore produced from the Bonanza and Magic mines near Wenden in the Ellsworth district, 317 tons of lead ore and 47 tons of zinc-lead ore from the Lucky Lead group near Bouse in the Plomosa district; 45 tons of lead ore from the Rialto mine in the Castle Dome district; and 61 ounces of placer gold from the Colorado River Valley property 50 miles north of Yuma in the Trigo district.

California

Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By R. B. Maurer and Leona Froehlich

GENERAL SUMMARY

SPURRED by the urgent need for base metals, California 1951 recoverable zinc production rose to the highest point since the war year 1945, whereas lead output fell but was second only to the State's record 1950 yield. Silver reflected its byproduct role, especially as a component of zinc and lead ores, and advanced over 1950. Copper output rose in 1951 owing to increases both as a byproduct metal and from copper ore. Gold, relatively unimportant quantitatively as a byproduct metal, declined to the lowest level since 1945 as a result of high operating costs plus progressive depletion of minable gravels and developed gold ore. The total value of gold, silver, copper, lead, and zinc recovered from materials sold or treated at 173 lode mines and 121 placer mines in 1951 was $21,700,575 compared with $22,081,859, the output of 243 lode mines and 186 placer mines in 1950, a drop of 2 percent.

Comparing 1951 with 1950, zinc output increased 27 percent in quantity and 63 percent in value; copper increased 43 percent in quantity and 66 percent in value; silver increased 7 percent in quantity and value; lead decreased 12 percent in quantity but increased 13 percent in value; and gold decreased 18 percent in quantity and value. Of the total value of the five metals gold comprised 55 percent; lead, 22 percent; zinc, 16 percent; silver, 5 percent; and copper, 2 percent.

Owing to its lead and zinc production, as well as important quantities of gold, silver, and copper, Inyo County led in total value of production of the five metals, contributing 35 percent of the State output. Nevada County ranked second in 1951, largely because of gold ore mined, and furnished more than 15 percent of the total value of the five metals. Sacramento County, third among the 32 producing counties, supplied nearly 15 percent, principally from gold dredging.

All tonnage figures reported herein are short tons and "dry weight"; that is, they do not include moisture. Yardage figures used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before treatment. The value of metal production has been calculated at the prices shown in table 1.

TABLE 1.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] (per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

[1] Price under authority of Gold Reserve Act of Jan. 31, 1934.
[2] Treasury buying price for newly mined silver, July 1, 1946 to date—$0.9050505 ($0.905 used in 1947 for calculating purposes).
[3] Yearly average weighted price of all grades of primary metal sold by producers. Price in 1947 includes bonus payments by Office of Metals Reserve for overquota production.

TABLE 2.—Mine production of gold, silver, copper, lead, and zinc in California in 1951 by months, in terms of recoverable metal [1]

Month	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)
January	33,148	100,446	96	1,233	761
February	33,435	91,957	74	1,245	758
March	33,479	94,376	73	1,284	810
April	30,602	107,633	70	1,240	701
May	31,662	100,142	70	1,129	709
June	28,588	92,072	56	1,074	782
July	26,127	91,153	63	1,184	748
August	26,468	81,394	100	919	741
September	23,263	76,076	52	903	671
October	24,414	101,745	77	1,193	1,004
November	23,193	107,242	124	1,371	1,110
December	25,353	100,983	66	1,192	807
Total	339,732	1,145,219	921	13,967	9,602

[1] Mine production comprises ore, gravel, or other mineral material sold or treated and metal recovered as natural gold or as bullion from cyanidation or amalgamation and the estimated recoverable metal (or gross metal as indicated) contained in concentrates, ores, tailings, and other mineral materials shipped directly to smelters or sold to ore buyers within the year.

Digitized by Google

Gold.—Gold output, including a relatively small quantity sold in the open market as "natural gold," deteriorated gradually in 1951 as the pinch of rising operating costs and manpower shortage became more acute.

The following 10 leading gold-producing properties in California in 1951, listing in order of output, yielded 81 percent of the total gold, the 5 leaders alone producing 61 percent: The Natomas Co., American River (Folsom) district, Sacramento County (dredging); Idaho Maryland Mines Corp. Brunswick-Idaho Maryland mine, Grass Valley-Nevada City district, Nevada County (gold ore); Yuba Consolidated Gold Fields Yuba unit, Yuba River district, Yuba County (dredging); Empire Star Mines Co., Ltd. Empire Star group, Grass Valley-Nevada City district, Nevada County (gold ore); Central Eureka Mining Co. Old Eureka mine, Mother Lode district, Amador County (gold ore); Yuba Consolidated Gold Fields Butte unit, Oroville district, Butte County (dredging); Capital Dredging Co., American River (Folsom) district, Sacramento County (dredging); the Original Sixteen to One Mine, Inc. Original Sixteen to One mine, Alleghany district, Sierra County (gold ore); Best Mines Co. Brush Creek mine, Downieville district, Sierra County (gold ore); and Fairview Placers, Trinity River district, Trinity County (dredging).

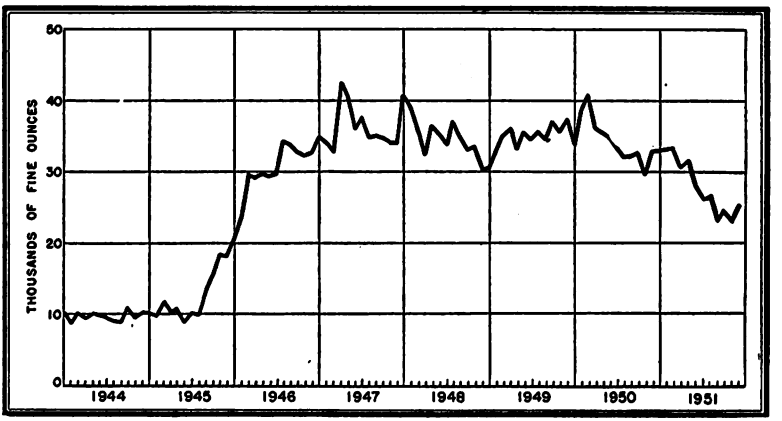

FIGURE 2.—Mine production of gold in California, 1944–51, by months, in terms of recoverable gold.

Silver.—The moderate rise in 1951 silver output reflected the stress on base-metal ore production, particularly lead, zinc-lead, and zinc ore. Of the State silver, 90 percent was derived from base-metal lode material and 10 percent from precious-metal lode material and gravels; only about 2 percent was recovered from straight silver ore.

The following five leading silver-producing mines, listed in order of output, yielded 85 percent of the State's total silver in 1951: Anaconda Copper Mining Co. Darwin group, Coso district (zinc-lead and lead ores) and Shoshone group, Resting Springs district (lead ore), both in Inyo County; Coronado Copper & Zinc Co. Afterthought mine, Cow Creek (Ingot) district, Shasta County (zinc ore); Penn Chemical Co., Inc. Penn mine, West Belt (Campo Seco) district, Calaveras County

Digitized by Google

(zinc ore); and L. D. Foreman & Co. Defense mine, Modoc district, Inyo County (lead ore).

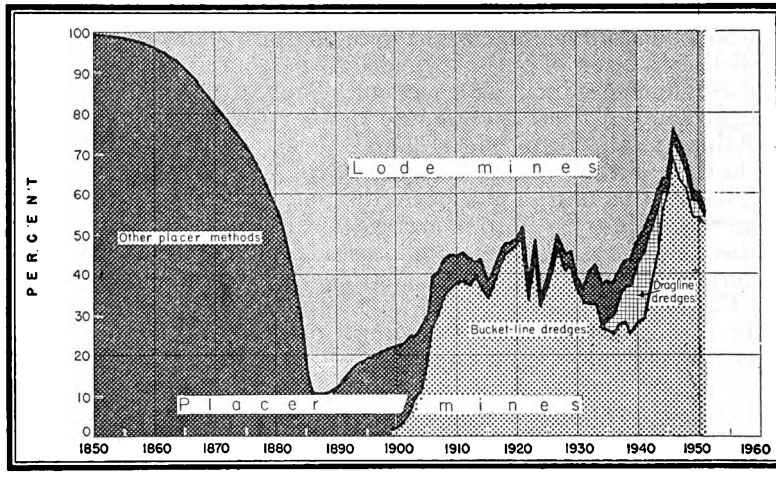

FIGURE 3.—Percentage of total California gold produced at lode and placer mine and by various methods of placer mining, 1850–1951.

TABLE 3.—Mine production of gold, silver, copper, lead, and zinc in California, 1947–1951, and total, 1848–1951, in terms of recoverable metal [1]

Year	Mines producing [2]		Material sold or treated (short tons) [3]	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value

1848–1951	----------	----------	[7]	66,817,363	1,474,345,351	[7]

[1] For historical data by years, see Minerals Yearbook, Review of 1940, p. 219.
[2] Excludes itinerant prospectors, "snipers," "high-graders," and others who gave no evidence of legal right to property.
[3] Includes commercial rock plants and tungsten mines that produced byproduct gold from gravels. By product gold is included with gold recovered, but material treated and average value per cubic yard refer only to straight gold dredging.
[4] Revised figures.
[5] Includes all placer operations using power excavator and washing plant, both on dry land; when washing plant is movable, outfit is termed "dry-land dredge."
[6] Includes all operations in which hand labor is principal factor in delivering gravel to sluices, long toms, dip boxes, pans, rockers, dry washers, etc.
[7] Complete data not available.

Copper.—Development of small properties in 1951 in some of California's copper districts resulted in moderate output of copper that aided in increasing the relative minor yield of the metal over 1950; but the principal source of copper continued to be ores treated primarily for other metals. The leading producers of recoverable copper in order of output were: Coronado Copper & Zinc Co. Afterthought mine, Cow Creek (Ingot) district, Shasta County (zinc ore); Penn Chemical Co., Inc. Penn mine, West Belt (Campo Seco) district, Calaveras County (zinc ore); Anaconda Copper Mining Co. Darwin group, Coso district (zinc-lead and lead ore) and Shoshone group, Resting Springs district (lead ore) both in Inyo County; and Donald Love, Bagdad-Chase mine, Buckeye district, San Bernardino County (copper ore).

Lead.—The Anaconda Copper Mining Co. Inyo County properties, the Darwin group, Coso district and Shoshone group, Resting Springs district, dominated California lead output in 1951 and furnished a large percentage of the State total. Substantial quantities of lead were recovered from Coronado Copper & Zinc Co. Afterthought mine ore and from flue dust accumulated at the site of the abandoned Kennett copper smelter, both in Shasta County. Those producers with moderate lead output included L. D. Foreman & Co., Defense mine, and Finley & Vignich, Minnietta mine, Modoc district; and Lippincott Lead Mines, Lead King (Lippincott) mine, Ubehebe district, all in Inyo County.

Zinc.—The rise in California 1951 zinc output is attributable largely to steady operation at the three major zinc-producing mines: Anaconda Copper Mining Co. Darwin group, Inyo County; Coronado Copper & Zinc Co. Afterthought mine, Shasta County; and the Penn Chemical Co., Inc. Penn mine, Calaveras County. Lead ore and concentrates from Anaconda Copper Mining Co. Shoshone group, Inyo County and Kennett smelter site flue dust, Shasta County, shipped to a smelter-fuming plant contained recoverable zinc. Some oxidized zinc ore from the Carbonate King Zinc mine, Ivanpah district, San Bernardino County, was treated at a fuming plant.

[1] Excludes itinerant prospectors, "snipers," "high-graders," and others who gave no evidence of legal right to property.
[2] Fresno and Mariposa County placer combined to avoid disclosure of individual output.
[3] Combined to avoid disclosure of individual output.
[4] Yuba County lode gold and lode silver included with Nevada County.
[5] From property not classed as a mine.

MINING INDUSTRY

The sharp drop in the number of California producing lode mines in 1951 is attributable largely to the decline in precious-metal mining. Owing to fixed prices for gold and silver, operators of lode mines retrenched, with the result that no extensive ore development was done at most mines and few new ventures were initiated. Placer mining, particularly dredging, likewise was adversely affected by the inflationary trend in the national economy coupled with the progressive exhaustion of profitable gravels. Also, higher freight rates and the growing competition for skilled manpower in the State's expanding industries, including tungsten mining, were deterrents to development at small marginal base-metal ore properties, particularly in more isolated regions of the State. Interest was shown in new base-metal properties, particularly West Belt district copper prospects, but the ore developed was not of great significance insofar as large reserves were concerned. The strike at nonferrous metal facilities from August 27 through September 6, 1951, caused some loss in California metal output, chiefly lead and zinc. Data on California mines were published.[1]

ORE CLASSIFICATION

California ores sold or treated in 1951 are classified in table 6. Definitions used in ore classification are given in the Gold and Silver chapter of this volume.

TABLE 6.—Mine production of gold, silver, copper, lead, and zinc in California in 1951, by class of ore or other source material, in terms of recoverable metal

Source	Number of mines [1]	Material sold or treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore:							
Dry gold	109	278,750	143,943	54,815	200	16,300	400
Dry gold-silver	2	1,645	699	13,802			
Dry silver	12	3,441	17	20,122	700	237,000	100
Total	119	283,836	144,659	88,739	900	253,300	500
Copper	8	1,553	442	4,109	151,900		
Lead	21	57,032	4,100	359,139	121,300	16,082,700	2,354,800
Lead-copper	1	55		730	3,000	14,700	3,500
Zinc	5	40,556	1,428	177,908	1,145,500	1,073,300	7,372,500
Zinc-lead	4	93,452	415	464,226	189,600	9,729,900	8,862,300
Total	35	192,648	6,385	1,006,112	1,611,300	26,900,600	18,593,100
Other "lode" material:							
Old tailings, etc.[2]	22	17,431	942	31,398	75,900	780,100	610,400
Copper precipitates	3	80			97,300		
Old slag and tungsten ore [3]	7	[4] 156	122	6,508	56,600		
Total	29	17,667	1,064	37,906	229,800	780,100	610,400
Total "lode" material	173	494,151	152,108	1,132,757	1,842,000	27,934,000	19,204,000
Gravel (placer operations)	121		187,624	12,462			
Total, all sources	294	494,151	339,732	1,145,219	1,842,000	27,934,000	19,204,000

[1] Detail will not necessarily add to totals because some mines produce more than one class of material.
[2] Metal recovered, by class of old tailings, flue dust, or pyritic ore residue, as follows: gold, 9,367 tons—507 ounces of gold, 1,003 ounces of silver, 7,500 pounds of copper; gold-silver, 2 tons—164 ounces gold, 2,253 ounces of silver; silver, 4,947 tons—165 ounces gold, 13,198 ounces silver, 11,700 pounds copper, 285,500 pounds lead; lead, 586 tons—3 ounces gold, 3,082 ounces silver, 800 pounds copper, 91,100 pounds lead; zinc-lead, 2,529 tons—103 ounces gold, 11,862 ounces silver, 55,900 pounds copper, 403,500 pounds lead, and 610,400 pounds zinc.
[3] Combined to avoid disclosure of individual output.
[4] Tungsten-ore tonnage not included.

METALLURGICAL INDUSTRY

Of the lode material from California mines sold or treated during 1951, 92 percent went to mills and 8 percent to smelters. Most of the ore milled was handled at company-owned metallurgical plants; the few mills that received custom material included: Burton Bros. Inc. (cyanidation), Butte Lode Mining Co. (cyanidation and amalgamation), and Mojave Mining & Milling Co. (concentration), Kern County; and Empire Star Mines Co., Ltd. (cyanidation), Nevada County. Improvements made at mills treating the complex base-metal ores in Shasta and Calaveras Counties resulted in higher zinc, lead, and copper content of concentrates produced. Addition of a 135-ton oxide section to Anaconda Copper Mining Co. Darwin flotation plant provided for expanded mine and mill production. Installation of a fuming unit at the American Smelting & Refining Co. Selby lead plant, Contra Costa County, was in progress. Recovery of

Digitized by Google

considerable zinc from slag piles was anticipated. During 1951 the Selby plant treated domestic material from 9 States and Alaska, as well as material from 14 foreign countries. The Lippincott Lead Co. reduced argentiferous lead ore in its blast furnace at Santa Ana, Orange County, operated in conjunction with a storage-battery plant; the furnace was moved to a site near Bonnie Clare, Nev., late in 1951. Data on California ores were published.[2]

TABLE 7.—Mine production of gold, silver, copper, lead, and zinc in California in 1951, by method of recovery and type of material processed, in terms of recoverable metal

Method of recovery and type of material processed	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)

[1] Includes concentrate and contained metal from tungsten ore.

REVIEW BY COUNTIES

ALPINE

Anaconda Copper Mining Co. acquired the Leviathan mine, Monitor district, a source of both copper and sulfur ores in prior years. The company planned to utilize sulfur ore to manufacture sulfuric acid at its Yerington, Nevada, copper project.

AMADOR

There was no lode mining of any consequence other than at the Central Eureka Mining Co. Old Eureka mine, Mother Lode district, where 38,400 tons of gold ore was milled compared to 39,993 tons in 1950. The Lorentz & Swingle dragline dredge, Cosumnes River district, led in production of placer gold.

Digitized by Google

BUTTE

Lode gold and silver produced was from small mines worked sporadically. Principal producers of placer gold were Yuba Consolidated Gold Fields' three bucket-line dredges, Oroville district, and the Thurman & Wright dragline dredge No. 3, Butte Creek district, moved from Mariposa County and put into operation October 16, 1951.

CALAVERAS

West Belt district base-metal mines overshadowed those of other County districts in 1951. The Penn mine (Penn Chemical Co., Inc.) produced copper, zinc, and gold concentrates from 19,873 tons of ore milled which yielded 771 ounces of gold, 39,020 ounces of silver, 441,100 pounds of copper, 87,200 pounds of lead, and 1,767,300 pounds of zinc. The Star and Excelsior mine (Trebor Corp.) and the Donner mine (Sierra Copper Co.), both copper properties, were under development in 1951 and made small shipments of ore. The Blackstone mine, East Belt district, was the leading lode-gold producer and the Mountain Gold Dredging Co. dragline dredge at Valley Springs, West Belt district (838 ounces of gold and 82 ounces of silver from 126,000 cubic yards of gravel) and the Gold Bar Mining Co. (successor to Alta Mining Co.), Altaville drift mine, Mother Lode district, led in placer-gold output.

EL DORADO

The Hazel Creek Mining Corp. Hazel Creek mine, East Belt district, was the outstanding producer of gold and silver in El Dorado county in 1951. In addition some lead was recovered from concentrate smelted. Calivada Development Co. prepared the El Dorado Copper mine, West Belt district, for further development and in addition to stockpiling 500 tons of milling ore shipped 18 tons of direct-smelting copper ore, which grossed 1 ounce of gold, 15 ounces of silver, 3,756 pounds of copper, and 547 pounds of zinc. The Bureau of Mines explored this property in 1944 and 1945. The River Pine Mining Co., Ltd., dragline dredge, Mother Lode district, leading producer of placer gold, operated 2 months only.

FRESNO

Some gold and silver were produced along the San Joaquin River, Friant district, by suction dredging and in conjunction with sand- and gravel-plant operation.

IMPERIAL

Holmestake Mining Co., Cargo Muchacho district, ceased milling Cargo Muchacho group gold ore in March 1951 to pursue tungsten-ore mining and milling.

Digitized by Google

INYO

The Anaconda Copper Mining Co. Darwin group, Coso district, continued as California's leading producer of silver, lead, and zinc, although the ore mined in 1951 was lower grade than 1950. To provide for increased output a 135-ton oxide section was added to the mill, and several additions were made to the surface establishment, including 10 new housing units. Shipments of tailings, slag, and dump ore from old workings by lessees augmented the group's total recoverable metal output. Anaconda's Shoshone group, Resting Springs district, followed the Darwin group closely in output, being the State's second-largest producer of silver and lead as well as an important producer of recoverable zinc and gold. Other Inyo County base-metal mines with important, although moderate output, owing largely to limited developed ore reserves, included the Defense mine, lead ore, the Minnietta mine, lead ore and lead concentrate, Modoc district; the Lippincott mine, zinc-lead and lead ores, and the Ubehebe mine, lead ore, Ubehebe district. Considerable tonnages of tailings and dump ore from inactive mines in the Cerro Gordo (Swansea) and Slate Range districts were consigned to a lead smelter. There was little activity in mining gold and silver ores.

KERN

Production of gold and silver in the Mojave district held up well owing largely to operation of Burton Bros., Inc., custom mill where ore from the Tropico and Cactus Queen mines, worked by Burton Mines, Inc., and lessees, the Whitmore group (Red Ink Mining Co.), and the Golden Queen group (N. W. Sweetser et al.), in addition to several smaller properties, was cyanided. Some high-grade silver ore from the Wegman group (Bert Wegman) was shipped directly to the smelter. The Yellow Aster mine (King Solomon Lease) led in Randsburg district gold production followed by the Butte Lode Mining Co. which also operated a custom mill. Basin Mining Co. produced moderate quantities of gold and silver at the Joe Walker mine, Green Mountain (Piute) district. Placer gold and silver was recovered incidental to sand and gravel operations in the Kern River district, and from Randsburg district dry washers and pannings. Mill tests were made on Black Hawk mine, Agua Caliente district, zinc ore.

LOS ANGELES

Lode gold and silver mining was small-scale and sporadic. By-product placer gold and silver were recovered at the Azusa Rock & Sand Co., San Gabriel district.

MADERA

Suction dredging was continued throughout 1951 in the Chowchilla River, Fresno River, Friant, and Hildreth districts; the Howell Bros. dredge, Chowchilla River district, led in production of gold and silver. Some copper precipitates were produced from the Daulton mine water, West Belt district.

[12] Friant district lies in Fresno and Madera Counties.
[13] Slate Range district lies in Inyo and San Bernardino Counties.
[14] Randsburg district lies in Kern and San Bernardino Counties.
[15] Browns Valley district, Yuba County lode gold and lode silver included with Grass Valley-Nevada City district, Nevada County.
[16] Dale district lies in Riverside and San Bernardino Counties.
[17] Includes values and quantities which cannot be shown separately for certain individual districts as indicated in the appropriate column by footnote reference 8.

Digitized by Google

MARIPOSA

Except for moderate outputs of gold and silver and recovery of some lead in concentrates from the Marble Springs mine (Glenn-Steintorf Co.), East Belt district, lode mining was very small-scale and sporadic. Thurman & Wright dragline dredge No. 3, largest producer of county gold and silver, terminated operations in the West Belt (Hunter Valley) district in June 1951; the boat was moved to Butte County.

MERCED

Snelling Gold Dredging Co. bucket-line dredge operated throughout the year in the Merced River district.

MONO

Sarita group, Masonic district, gold ore was cyanided during 1951 by Sarita Milling Co.

NEVADA

The Grass Valley–Nevada City district continued to be the State's principal producer of lode gold, largely from the Idaho Maryland Mines Corp. Brunswick-Idaho Maryland mine and the Empire Star Mines, Co., Ltd., Empire Star group. The Ancho Erie Mining Co. closed the Ancho & Erie groups, Washington district, September 30, 1951. Chief placer mines were Minona Mining Co., French Corral district, and Crescent Pacific Mining Co., Washington (North Bloomfield) district. Gravel at both properties was moved mechanically to nonfloating washing plants.

PLACER

The Mary Len mine (A. H. L. Mining Co.), Auburn (Penryn) district, operated from January to July 1951; 212 tons of ore milled yielded values in gold and silver. The American Hill mine, Last Chance district, sluiced by W. B. Pendleton, led in output of placer gold.

RIVERSIDE

Precious-metal mining was small scale. Dan Figueroa & Sons developed the Bald Eagle mine, Ironwood district, and shipped 181 tons of direct smelting ore that grossed 1,186 ounces of silver, 52,415 pounds of lead, and 1,901 pounds of zinc.

SACRAMENTO

The American River (Folsom) district, by virtue of dredging and gold recovered at commercial sand and gravel plants, was the State's leading placer district; the Natomas Co. seven bucket-line dredges, the Capital Dredging Co. bucket-line dredge, and the General Dredging Co. dragline dredge were the principal producers of placer gold. Cosumnes Gold Dredging Co. bucket-line dredge, Cosumnes River district, closed late in 1951, also had important gold output.

Digitized by Google

SAN BERNARDINO

Several small properties developed precious-metal ores, but the largest output was from the Rambler & Hill Top claims, Black Hawk district; 121 tons of gold ore milled grossed 228 ounces of gold and 111 ounces of silver. Base-metal mines also operated on a small scale and included the Bagdad-Chase, Buckeye district, copper ore; Carbonate King mine, zinc-lead and lead ores, and Mohawk mine, lead ore, Clark Mountain district; Carbonate King Zinc mine, Ivanpah district, zinc ore; and Sagamore mine, New York Mountains district, lead-copper ore. Some copper was recovered at Barstow, by milling Hoffman Estate tailings, largely from the old Bagdad-Chase mine.

SAN JOAQUIN

The Gold Hill Dredging Co. Lower Comanche bucket-line dredge, the county's sole operation producing gold and silver, closed in June 1951.

SHASTA

Led by the Coronado Copper and Zinc Co. Afterthought mine, Cow Creek (Ingot) district, which produced gold, silver, copper, lead, and zinc from its dwindling reserves of zinc ore, metal output rose sharply in 1951. Considerable zinc, lead, and copper, as well as gold and silver, were recovered from slag and flue dust shipped from sites of abandoned copper smelters in the Bully Hill and Flat Creek districts. Following a study of the area by the U. S. Geological Survey, exploration was begun December 1951 at the Bully Hill and Rising Star mines, Bully Hill district, which had substantial outputs of copper, zinc, gold, and silver, before 1928. The Mountain Copper Co. planned expansion of operations at its pyritic ore body in the Flat Creek district with eventual extraction of contained metals by leaching. Lode gold mining was quiescent, and placer mining waned after April 1951, when the Thurman Gold Dredging Co. bucket-line dredge, Redding district, leading producer of placer gold, was dismantled.

SIERRA

The Original Sixteen to One mine, Alleghany district, and Brush Creek mine (Best Mines Co.) led in production of gold and silver from gold ore milled.

SISKIYOU

Lode-gold mining was sporadic,. and placer-mining output fell sharply after March 1951, when Yuba Consolidated Gold Fields Siskiyou unit bucket-line dredge, leading producer of gold in Siskiyou County, terminated dredging in the Scott River district.

STANISLAUS

The La Grange Gold Dredging Co. bucket-line dredge No. 4, the only boat that operated in the county in 1951, terminated dredging in the Tuolumne River district June 1951.

Digitized by Google

TRINITY

The Fairview Placers bucketline dredge at Minersville, Trinity River district, led the county in producing gold and silver. Bucketline dredges worked, respectively, at Coffee Creek and near Weaverville, Trinity River district, closed before December 1951. Hydraulic mining waned, and lode gold mining was small scale. Ore depletion terminated activity at the Copper King copper mine, Forest Glen district; 39 tons of direct smelting ore shipped grossed 11 ounces of silver and 3,338 pounds of copper.

TUOLUMNE

Gold and silver produced was largely from pocket mines worked in the East Belt and Mother Lode districts.

YUBA

Except the operation of Yuba Consolidated Gold Fields Yuba unit, Yuba River district, comprising five bucket-line boats engaged principally in deep dredging, placer mining declined in other districts. The Empire Star Mines Co., Ltd., lessee-operated Browns Valley group, Browns Valley district, produced gold and silver in conjunction with the company's Nevada County mines.

OTHER COUNTIES

Rehabilitation of the Alta copper mine, Low Divide district, Del Norte County, worked between 1860 and 1870, was begun. Occasional operation of small properties resulted in minor outputs of gold and silver from Humboldt, Modoc, and Plumas Counties. San Mateo County beach sands yielded minor quantities of gold and silver. Test shipments of copper ore to smelters were made from the Powell mine, Camp Wishon district, Tulare County.

Colorado
Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By A. J. Martin

GENERAL SUMMARY

ECONOMIC factors that affected production of gold, silver, copper, lead, and zinc in Colorado in 1951 were essentially the same as during the closing months of 1950, after prices of most commodities had risen sharply and larger expenditures for national defense had been authorized by Congress as a result of the outbreak of fighting in Korea. The rise in wages and cost of materials, with no change in the domestic price of gold, accentuated the depression in straight gold mining. On the other hand, the advance in prices of and strong demand for copper, lead, and zinc stimulated mining in the districts producing chiefly base metals or gold and silver along with important quantities of the base metals. The output of zinc was the largest in quantity since 1917 and the highest in value since commercial recovery of zinc from Colorado ores was begun in 1885. Lead production, increasing for the fifth consecutive year, was the largest in quantity since 1927 and, like zinc, established a new record for value. Gains in quantity over 1950 were 22 percent for zinc and 12 percent for lead. Copper output increased 2 percent in quantity. Gold production decreased 11 percent and silver 20 percent from 1950. The total value of the output of the five metals, of which 79 percent was in zinc and lead, was $38,931,539 in 1951 compared with $29,323,268 in 1950.

The decrease in the State output of gold and silver was due mainly to a decline in the average gold and silver content of the base-metal and complex ores mined; some of the decrease in gold was due to lower production from placer operations. Mining on a substantial scale was resumed in the Cripple Creek gold district in April 1951, when the new 1,000-ton Carlton custom mill of the Golden Cycle Corp. completed preliminary test runs and began buying ore.

All tonnage figures reported herein are short tons and "dry weight"; that is, they do not include moisture. The value of production has been calculated at the prices shown in table 1.

Gold.—Production of gold in Colorado totaled 116,503 fine ounces in 1951 compared with 130,390 ounces in 1950. The average gold content of the base-metal ores mined declined sharply, and less gold was recovered from placers. Gold production in the Cripple Creek district increased from 5,779 ounces in 1950 to 27,699 ounces in 1951 owing to reopening of a number of mines that had shut down early in 1949 to await completion of the 1,000-ton Carlton custom mill of the

TABLE 1.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] (per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

[1] Price under authority of Gold Reserve Act of Jan. 31, 1934.
[2] Treasury buying price for newly mined silver July 1, 1946, to date—$0.9050505 ($0.905 used in 1947 for calculating purposes).
[3] Yearly average weighted price of all grades of primary metal sold by producers. Price in 1947 includes bonus payments by Office of Metals Reserve for overquota production.

Golden Cycle Corp. The mill began commercial operations in April 1951.

The Upper San Miguel district again ranked first in gold production, Cripple Creek second, California (Leadville) third, Fairplay fourth, and Animas fifth. Dry gold and silver ores yielded 35 percent of the total gold; zinc-lead and zinc-lead-copper ores 49 percent; other ores, old slag, old tailings, and mill clean-ups 4 percent; and placers 12 percent. The leading gold-producing properties, in order of rank, were: Treasury Tunnel-Black Bear (Idarado) group in San Miguel County; Resurrection group at Leadville; Smuggler Union group (Telluride Mines) at Telluride; South Platte Dredging Co. connected-bucket dredge near Fairplay; and Ajax (Golden Cycle Corp.) group at Cripple Creek.

Silver.—Colorado mines produced 2,787,882 fine ounces of silver in 1951 compared with 3,492,278 ounces in 1950. The decrease was due to a decline in the average silver content of the complex and base-metal ores mined. Zinc-lead and zinc-lead-copper ores yielded 54 percent of the total silver in 1951; dry gold and silver ores 31 percent; and other ores, old slag, old tailings, mill clean-ups, and placer gravel 15 percent. The leading producers of silver were the Treasury Tunnel-Black Bear (Idarado) group in San Miguel County, Eagle mine in Eagle County, Shenandoah-Dives group near Silverton, Emperius Mining Co. group at Creede, and Resurrection group at Leadville.

TABLE 2.—Mine production of gold, silver, copper, lead, and zinc in Colorado in 1951, by months, in terms of recoverable metal [1]

Month	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)
January	10,125	293,895	337	2,801	4,798
February	8,462	249,772	265	2,268	4,420
March	9,009	296,948	378	2,788	5,375
April	6,639	229,848	294	2,768	4,932
May	8,731	225,347	272	2,485	4,485
June	8,740	228,440	282	2,551	4,701
July	10,006	242,094	249	2,528	4,344
August	9,523	234,562	243	2,619	4,982
September	10,104	235,222	260	2,568	4,796
October	12,515	182,273	212	2,457	4,404
November	10,483	179,345	207	2,293	4,401
December	12,166	190,136	213	2,210	4,076
Total	116,503	2,787,882	3,212	30,336	55,714

[1] Mine production comprises ore, gravel, or other mineral material sold or treated and metal recovered as natural gold or as bullion from cyanidation or amalgamation and the estimated recoverable metal (or gross metal as indicated) contained in concentrates, ores, tailings and other mineral materials shipped directly to smelters or sold to ore buyers within the year.

1858–1951			[3]	39,730,535	884,445,689	745,170,388	580,913,798

Year	Copper		Lead		Zinc		Total value
	Short tons	Value	Short tons	Value	Short tons	Value	
1947	2,150	$903,000	18,696	$5,384,448	38,745	$9,376,290	$23,868,179
1948	2,298	997,332	25,143	9,001,194	45,164	12,013,624	30,155,337
1949	2,403	946,782	26,853	8,485,548	47,703	11,830,344	27,474,322
1950	3,141	1,306,656	27,007	7,291,890	45,776	13,000,384	29,323,268
1951	3,212	1,554,608	30,336	10,496,256	55,714	20,279,896	38,931,539
1858–1951	263,915	71,993,747	2,589,917	279,571,199	1,572,300	269,760,926	2,086,685,359

[1] Includes recoverable metal content of gravel washed (placer operations), ore milled, old tailings or slimes re-treated, and ore, old slag or tailings shipped to smelters during the calendar year indicated.
[2] Does not include gravel washed.
[3] Figure not available.

Copper.—The State output of recoverable copper in 1951 was 3,212 short tons compared with 3,141 tons in 1950. The Idarado Mining Co., which makes a copper concentrate from complex gold-silver-copper-lead-zinc ore mined in San Miguel County, was again the only substantial producer of copper in the State.

Lead.—The mine output of lead in Colorado, increasing for the fifth year in succession, rose from 27,007 short tons in 1950 to 30,336 tons in 1951. San Miguel County contributed 27 percent of the total, Lake County 20, San Juan 15, Eagle 14, Dolores 7, Ouray and Mineral

TABLE 4.—Gold and silver produced at placer mines in Colorado, 1947–51, in fine ounces, in terms of recoverable metal

Year	Small-scale hand methods [1]		Gravel mechanically handled				Total	
			Nonfloating washing plants [2]		Bucket-line and dragline dredges			
	Gold	Silver	Gold	Silver	Gold	Silver	Gold	Silver
1947	243	52	930	156	16,400	3,243	17,573	3,451
1948	106	29	662	103	12,479	2,680	13,247	2,812
1949	137	33	775	116	12,231	2,652	13,143	2,801
1950	83	21	1,246	196	18,084	3,522	19,413	3,739
1951	30	7	[3]	[3]	[3] 13,563	[3] 2,288	13,593	2,295

[1] Includes all operations in which hand labor is principal factor in delivering gravel to sluices, long toms, dip boxes, pans, rockers, dry washers, etc.
[2] Includes all placer operations using power excavator and washing plant, both on dry land; when washing plant is movable, outfit is termed "dry-land dredge."
[3] Production by nonfloating washing plants included with that by bucket-line dredges; Bureau of Mines not at liberty to publish separately.

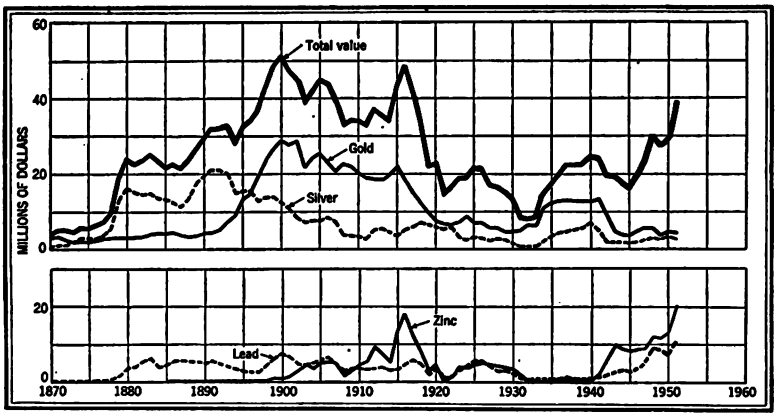

FIGURE 1.—Value of mine production of gold, silver, lead, and zinc and total value of gold, silver, copper, lead, and zinc in Colorado, 1870–1951. The value of copper has been less than $2,000,000 annually, except in a few years.

each 4, and other counties together 9 percent. Zinc-lead and zinc-lead-copper ores yielded 69 percent of the lead; zinc ore 14; gold and silver ores 9; lead ore 7; and copper ore, old slag, mill cleanings, and old tailings 1 percent. The larger lead-producing mines, in order of rank, were: Resurrection group; Treasury Tunnel-Black Bear (Idarado) group; Eagle mine; Smuggler Union (Telluride Mines) group; and Shenandoah-Dives group.

Zinc.—Production of recoverable zinc in Colorado in 1951 was 55,714 tons—an increase of 22 percent over 1950. Eagle County produced 52 percent of the total, San Miguel County 17, Lake 15, Dolores 5, San Juan 3, Gunnison 2, and other counties 6 percent. Zinc, zinc-lead, and zinc-lead-copper ores yielded 98 percent of the total production.

All the State's principal producers operated steadily throughout the year. The total number of mines, prospects, and dumps that contributed to the output of recoverable zinc was 100, the same as in 1950. The leading zinc-producing mines, in order of rank, were: Eagle mine at Gilman, Resurrection group at Leadville, Treasury Tunnel-Black Bear (Idarado) in San Miguel County, Smuggler Union (Telluride Mines) at Telluride, and Rico Argentine at Rico.

MINING AND METALLURGICAL INDUSTRY

The rank in value of the individual metals recovered from Colorado ores and gravels has changed greatly in recent years. Gold ranked first from 1858 to 1873, silver from 1874 to 1896, gold again from 1897 to 1942, and zinc from 1943 to 1951. Until 1943 the combined value of the copper, lead, and zinc had not exceeded that of the gold and silver except in 1916 and from 1925 to 1930. In 1941 gold and silver represented 77 percent and the base metals 23 percent of the total value of the five metals, but in 1951 gold and silver represented only 17 percent and the base metals a record high of 83 percent.

The shift to mining of predominantly base-metal ores was brought about during World War II by Government restrictions upon production of gold and the subsidies to producers of copper, lead, and zinc. In 1947 the prices of the base metals were decontrolled and could be raised to meet the rising cost of labor and materials, whereas, because of the fixed price of gold, straight gold or gold-silver mining became unprofitable, except for unusually rich mines.

Digitized by Google

In 1951 the favorable outlook for sustained demand for copper, lead, and zinc stimulated activity in exploration and development. Several mining companies carried on intensive development campaigns on their properties, and the Bureau of Mines continued driving the Leadville drainage tunnel.

A new program of Government assistance in financing exploration in search of reserves of strategic and critical minerals, authorized by the Defense Production Act of 1950, was undertaken by the Defense Minerals Administration. Colorado projects for copper, lead, and zinc approved under the program during 1951 totaled 22, involving $879,042 in combined Government and private capital, to be contributed on a 50–50 basis. Three of the projects, involving a total of $88,446, were canceled by mutual agreement, leaving $790,596 spent or available as of December 31, 1951. Repayment of the Government's contribution, without interest, through a royalty on net returns from products sold, is required if ore is discovered or delineated and the ore is mined within 10 years of the date of the contract.

Mills in Colorado operating all or part of the year on ores of gold, silver, copper, lead, and zinc totaled 31 in 1951 and 32 in 1950. Those active in 1951 comprised 27 flotation mills—6 with daily capacities ranging from 600 to 1,100 tons and 21 ranging from 50 to 300 tons, and 4 gravity mills of 50, 30, 15, and 5 tons capacity. The foregoing include the new 1,000-ton Carlton custom mill of the Golden Cycle Corp. in the Cripple Creek district, which employs roasting (in fluosolids reactor) and cyanidation to recover gold in the form of bullion from gold-pyrite flotation concentrate, with cyanidation of the flotation tailings. Some of the other flotation mills use jigs in the ball-mill classifier circuit to recover coarse gold for amalgamation.

Markets for custom zinc-lead and complex milling ores were provided by mills of the Resurrection Mining Co. at Leadville, the Shenandoah-Dives Mining Co. at Silverton, and the American Zinc, Lead & Smelting Co. at Ouray. Several scattered small mills treated custom ore on the basis of a fixed charge per ton, usually $4 for bulk concentration and $5 for selective concentration.

The Arkansas Valley smelter at Leadville purchases most of the lead, lead-copper, and siliceous gold-silver concentrates and direct-smelting ores. Custom mills and smelters in the Salt Lake Valley, Utah, purchase zinc-lead milling ores, bulk concentrates, and lead concentrates from some Colorado areas. Zinc concentrates are shipped to Amarillo, Corpus Christi, and Dumas, Tex.; Depue, Ill.; Palmerton, Pa.; and Anaconda and Great Falls, Mont. Copper concentrate is shipped to the Garfield, Utah, and El Paso, Tex., smelters.

ORE CLASSIFICATION

Definitions used in ore classification are given in the Gold and Silver chapter of this volume. Tables 6, 7, 8, and 9 show details of Colorado ores milled and smelted in 1951, by class of ore and by method of metal recovery.

Digitized by Google

TABLE 6.—Mine production of gold, silver, copper, lead, and zinc in Colorado in 1951, by class of ore or other source material, in terms of recoverable metal

Source	Number of mines [1]	Material sold or treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore:							
Dry gold	43	115,081	28,362	6,720	185	7,588	----------
Dry gold-silver	18	258,929	12,298	650,078	1,369,372	5,199,255	1,302,985
Dry silver	17	12,751	377	217,085	12,768	395,499	69,962
Total	77	386,761	41,037	873,883	1,382,325	5,602,342	1,372,947

Total	--------	12,637	876	33,266	4,505	451,590	65,180
Total "lode" material	196	1,578,466	102,910	2,785,587	6,424,000	60,672,000	111,428,000
Gravel (placer operations)	21	----------	13,593	2,295	----------	----------	----------
Total, all sources	217	1,578,466	116,503	2,787,882	6,424,000	60,672,000	111,428,000

[1] Detail will not add to totals because some mines produce more than one class of ore.
[2] Includes zinc-lead-copper ore, for which the Bureau of Mines is not at liberty to publish separate figures.
[3] Includes 415 tons gold mill cleanings, 38 tons lead mill cleanings, 31 tons lead tailings, 164 tons zinc-lead tailings.

TABLE 7.—Mine production of gold, silver, copper, lead, and zinc in Colorado in 1951, by method of recovery and type of material processed, in terms of recoverable metal

Method of recovery and type of material processed	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Lode:

REVIEW BY COUNTIES

ADAMS

Placer gold was recovered as a byproduct in sluices at 6 sand and gravel plants on Clear Creek northwest of Denver.

BOULDER

The production of gold in Boulder County in 1951 was the lowest since 1945, but that of silver was the largest since 1922. The copper and lead output was recovered as a byproduct of gold, silver, and fluorspar mining. No zinc was recovered from Boulder County ores in 1951; production in 1950 was 3 tons.

The old Caribou mine in the Grand Island district, reopened in 1947 by the Consolidated Caribou Silver Mines, Inc., produced most of the county output of silver in 1951.

At Jamestown the Ozark-Mahoning and General Chemical companies recovered lead-silver-gold-copper concentrate as a byproduct in the beneficiation of fluorspar. The Cash mine at Gold Hill and the Franklin (Wood Mountain) and Nancy mines at Sugarloaf, formerly substantial gold producers, shipped some ore during the first few months of 1951.

CHAFFEE

At the Mary Murphy mine in the Chalk Creek district, an important producer in the past, S. E. and W. E. Burleson erected a new building, reconditioned other buildings and old mine workings, and did some stoping between the 1,400- and 1,300-foot levels; ore shipped in 1951 totaled 252 tons containing 28 ounces of gold, 465 ounces of silver, 26,906 pounds of lead, 1,864 pounds of copper, and 50,207 pounds of zinc.

CLEAR CREEK

The Mendota-Frostberg and Terrible-Dunderberg mines at Silver Plume and the Stevens mine and dump in the Argentine district each produced considerable zinc-lead ore in 1951. Most of the ore was treated in the Silver Spruce and Black Eagle mills near Idaho Springs, but part of the Terrible-Dunderberg ore was shipped to the Resurrection mill at Leadville. In the Trail Creek district the Montana Mining & Development Co. mill on the Lamartine property treated dump ore containing gold, silver, and some lead. The Nabob mine near Lawson shipped high-grade silver-lead ore, and the Franklin near Idaho Springs shipped zinc-lead-silver-gold ore. Gold output from the Dixie mine near Idaho Springs was less than in 1950. The mill of Front Range Mines, Inc., at Dumont treated company ore from the Mattie-King Solomon group in Clear Creek County and the Strong in Teller County and custom ore from three mines in Boulder County. Exploration projects with Government participation in financing on a 50-50 basis under a Defense Minerals contract were carried on at the Grizzly mine and the Burleigh tunnel.

[3] Includes amounts recovered from lead-silver-gold-copper concentrates produced as byproduct of beneficiation of fluorspar at 2 plants
[4] Small quantity of gold and silver from Sugar Loaf district is included with the California (Leadville) district.

Digitized by Google

CUSTER

In 1951 the Defender Mining Co. sank 80 feet of shaft and drove 396 feet of drifts at the Defender mine at Silver Cliff and shipped 264 tons of lead-zinc-silver ore.

DENVER

George W. Baugh sold some gold recovered in testing placer-mining equipment on Platte River.

DOLORES

All of the Dolores County output of gold, silver, copper, lead, and zinc in 1951 came from the Pioneer (Rico) district. The Rico Argentine Mining Co. group, equipped with a 135-ton mill, operated continuously, and its production (chiefly zinc, lead, and silver) was much larger than in 1950, when operations in the first half of the year were confined mostly to development. Lead-silver ore from the Forest-Wedge group and zinc-lead-silver ore from the Union Carbonate were shipped direct to smelters. The St. Louis mine produced some high-grade gold ore.

EAGLE

Red Cliff (Battle Mountain) District.—This District contributed the entire Eagle County output of the five metals in 1951. The Eagle mine of the New Jersey Zinc Co., Empire Zinc Division, at Gilman, operated continuously and at a higher production rate than in 1950. The mill is completely underground, in an excavation cut in granite in Eagle Canyon, and has a capacity exceeding 1,000 tons daily. The principal ore bodies occur as replacements in a flat-dipping bed of limestone. They are generally massive, with a core of iron-copper-silver-gold ore surrounded by an outer layer of zinc-lead ore. The zinc-lead ore is treated in the mill, and the iron-copper-silver-gold ore is shipped crude to smelters. The mine is opened by a main haulage tunnel on the 16th level (with its portal at the ore bins in Eagle Canyon), a vertical service shaft bottomed on the 16th level, raises from the 16th level, and a series of inclines from the 16th to the 24th levels. The entire operation is completely mechanized. Electric battery motors are used for underground haulage.

FREMONT

Some material containing zinc, lead, and silver was shipped from a slag dump at Florence.

GARFIELD

A car of zinc-lead-silver ore shipped late in 1950 from the Sunshine mine 15 miles north of Rifle was credited to 1951 production.

GILPIN

Mining in Gilpin County in 1951 was confined to small-scale operations. The producing properties were the West Notoway dump, Smith (Lone Star) group, We Got Em mine, and several small

Digitized by Google

placers. A lead-zinc exploration project was undertaken at the Gilpin-Eureka-Essex group, with Government participation under a Defense Minerals contract.

GUNNISON

The Callahan Zinc-Lead Co., Inc., operated its Akron-Erie group and 100-ton mill at Whitepine and was a steady shipper of zinc and lead-silver concentrates. Exploration was expanded under a Defense Minerals contract, providing joint financing by the company and the Government on a matching-funds basis. At the Keystone mine near Crested Butte the Park City Consolidated Mines Co. and the American Smelting & Refining Co. carried on development throughout the year; the ore removed in development was stockpiled at the mine. The Crested Butte Mining & Milling Corp. Daisy group, Slate River Mining Co. Macawber mine (reopened after having been idle for a long period), and Evans Basin Mining Co. Chautauqua mine shipped zinc-lead-silver ore, and the Star mine at Tin Cup (worked by John Lambertson) shipped lead-silver ore. The Kanarado Mining & Development Co. acquired the old Carter gold mine near Ohio and worked on remodeling the mill for handling sulfide ores containing lead and zinc.

HINSDALE

At the Ute and Ulay property in the Galena district the Colorado Standard Lead Zinc Mines, incorporated December 11, 1950, worked in 1951 on mine development, reconditioning old mine workings, repairing and improving the flotation mill, and installing a Diesel-electric power plant. The county output of ore, totaling 211 tons, came from the Yellow Medicine, Hoosier Boy, and Gold Quartz mines.

JEFFERSON

On Clear Creek east of Golden, W. B. Kerkling operated a placer mine, and several sand and gravel plants recovered gold as a byproduct.

LAKE

California (Leadville) District.—Nearly all the Lake County output of the five metals in 1951 came from the Leadville district. The bulk of the ore was produced by the Resurrection group of mines, operated since 1942 by the Resurrection Mining Co. The mine is opened by a 1,323-foot vertical shaft, six levels, and a 4-mile tunnel (old Yak) which intersects the shaft. The ore was concentrated in the company 600-ton selective-flotation mill, which also handled custom ores from Chaffee, Clear Creek, Custer, Gilpin, Lake, Park, Saguache, and Summit Counties.

The Arkansas Valley smelter of the American Smelting & Refining Co. operated continuously. The smelter treats lead, lead-copper, lead-copper-gold-silver, and gold and silver ores and concentrates purchased from operators in nearly all the active mining districts of Colorado and concentrates, residues from zinc smelters, and other material from outside the State. Receipts of purchased material in 1951 totaled 110,160 tons compared with 101,701 tons in 1950. Besides operating its smelter, the company continued its development

Digitized by Google

project in the Ibex-Sunday area at Leadville; ore produced in development was shipped to the Resurrection mill.

Other producers at Leadville included the Dolly B, Fortune, New Monarch, and Valley mines and several dumps.

The Leadville drainage tunnel, an unfinished World War II project of the Bureau of Mines on which driving was resumed September 20, 1950, with the Utah Construction Co. as contractor, had been advanced during 1950 from 6,600 feet from the portal to 7,440 feet as of December 20, 1950; at the end of December 1951 it had been lengthened to 10,730 feet. In addition, 291 feet had been driven on a Downtown lateral, 191 feet on a lateral connecting the tunnel with the Hayden shaft (which was reconditioned by the Cadwell Mining Co. in the course of an exploration project), and 36 feet on the Robert Emmet lateral. The peak flow of water from the tunnel was 3,765 gallons per minute on July 5; the flow at the end of December was about 2,580 g. p. m., and accumulated water in workings above the tunnel level in the Carbonate Hill and Freyer Hill basins was being drained at a satisfactory rate.

LARIMER

The Black Hawk No. 1 and No. 2 claims in the Prairie Divide district, under development by Cherokee Mines as a source of uranium, had an incidental output of 55 tons of zinc ore in 1951.

MINERAL

All the output of metals from Mineral County in 1951 came from the Creede district. The Emperius Mining Co. continued to operate its large group of mines and 120-ton flotation mill. Ore produced totaled 45,230 tons. Other district output comprised 98 tons of high-grade silver-lead ore from the Phoenix mine and 94 tons from the Solomon group.

OURAY

The Camp Bird mine in the Sneffels district, equipped with a 125-ton flotation mill, is the principal producer of metals in Ouray County. The mine, operated by King Lease, Inc., has been a steady producer since it was reopened by Joseph King in 1926; it was also very productive from 1896 to 1916.

There were 16 other small-producing mines and prospects in Ouray County in 1951. The American Zinc, Lead & Smelting Co. continued to buy ore for treatment in its custom flotation mill at Ouray. The Bachelor Development Co. worked on an exploration project, financed by the company and the Government on a 50–50 basis under a Defense Minerals contract.

PARK

The South Platte Dredging Co. continued to operate its electrically powered connected-bucket dredge on South Platte River near Fairplay and ranked fourth in the State in gold production in 1951. The only other substantial metal producer in Park County was the Buckskin Joe Mines, Ltd., which worked the Phillips group in Buckskin Gulch and shipped gold-zinc-lead-silver ore to the Resurrection mill at Leadville.

Digitized by Google

PITKIN

The Midnight Mining Co. operated its Midnight silver-lead-zinc mine at Aspen and ran the mill occasionally. Herron Bros. shipped some silver-lead ore from the Henry Clay group.

SAGUACHE

Operators in Saguache County shipped their ore to custom mills and smelters outside the county. The Antoro mine at Bonanza, operated since 1947 by S. E. and W. E. Burleson, shipped 2,696 tons of ore. The Rawley mine and five other small producers together shipped 1,255 tons of ore during the year.

SAN JUAN

The Shenandoah-Dives Mining Co. continued in 1951 to operate as a unit its Shenandoah-Dives-Mayflower consolidated group of claims and the leased Silver Lake group; ore produced was treated in the company 700-ton mill. Since the company began large-scale mining in 1928 it has mined and milled 4,034,797 tons of gold-silver-lead-copper-zinc ore on company account (to the end of 1951) and in addition 147,772 tons of custom ore mined by other operators. Company ore milled in 1951 totaled 196,097 tons and custom ore 26,118 tons.

The Lead Carbonate mine and 50-ton mill operated throughout the year. The Old Hundred Gold Mining Co., operating the Gary Owen-Old Hundred group, was a substantial producer of ore, part of which was shipped to custom mills and part of which was treated in the reconditioned company mill put in operation in July. Other producers of more than 1,000 tons of ore, in order of tonnage of ore shipped, were the Pride of the West mine, Green Mountain (mine and dump), Columbus, Galena Queen, Silver Ledge, May Day, Great Eastern-Sioux City, and Little Nation. A total of 2,842 tons of ore and clean-up material was shipped from 17 mines, prospects, and dumps and a mill site (not counted as a mine) that produced less than 1,000 tons each during the year.

SAN MIGUEL

San Miguel County again ranked first in the State in production of gold, silver, copper, and lead and second in zinc. Most of the output came from the Upper San Miguel district, reviewed separately in the next paragraph. However, the Silver Bell group in the Ophir district, operated since 1946 by the Silver Bell Mines Co., continued to be a substantial producer of gold-silver-lead-copper ore. The capacity of the mill, formerly 150 tons daily, was raised to 175 tons, and a tungsten concentrating section was nearly completed in 1951. The company also purchased the Carbonero mine and began preparing it for operation. The Andrus group in eastern San Miguel County shipped some ore in 1951.

Upper San Miguel District.—The Idarado Mining Co. increased the tonnage of ore mined from its Treasury Tunnel-Black Bear-Ajax group

Digitized by Google

for the sixth consecutive year and continued its extensive exploration and development campaign. The ore carries zinc, lead, gold, silver, and copper and is treated in the company 750-ton mill at the portal of the 12,000-foot Treasury tunnel, which extends from the mine workings into Ouray County. Products of the mill are zinc concentrate, lead concentrate, and copper concentrate (all enriched by gold and silver), and gold-silver bullion (obtained by amalgamating a jig hutch product).

Telluride Mines, Inc., operated its Smuggler Union-Montana group and 600-ton mill at about the same crude-ore tonnage rate as in 1950. The mill products were high-grade gold-lead-silver jig concentrate, gold bullion (obtained by amalgamating jig concentrate), flotation lead-gold-silver-copper concentrate, and flotation zinc concentrate. Completion of the ore pass connecting the new 7,000-foot mill-level tunnel with the mine workings 1,100 feet above permitted underground transportation of the ore to the mill instead of surface haulage by aerial tram as in the past. Mechanization of mining has been virtually completed.

SUMMIT

The largest individual producer in Summit County in 1951 was the Wellington mine at Breckenridge, which shipped 3,273 tons of ore. The next-largest producers were the Sts. John mine at Montezuma, with 2,326 tons; Chautauqua, with 953 tons; Allen Emory, with 734 tons; and Silver King, with 443 tons.

TELLER

Cripple Creek District.—Metal mining in Teller County is confined to the Cripple Creek gold district. Nearly all the ore produced in 1951 was treated in the new 1,000-ton Carlton custom mill of the Golden Cycle Corp. This mill was built to replace the old Golden Cycle mill at Colorado Springs as a market for Cripple Creek ore and began treating ore on a commercial basis early in April 1951. It was designed to include the latest improvements in methods of ore handling and gold recovery applicable to Cripple Creek ore. Several months of operation at less than rated capacity were required to test and adjust equipment and make changes and additions found necessary to achieve the best results throughout the mill, some sections of which use processes being applied commercially to Cripple Creek ore for the first time. The continued rise in wages and cost of materials, with no change in the domestic price of gold, retarded reopening of some mines that were shut down in 1949 to await completion of the mill and led to the closing of several of the mines that did reopen.

The principal district producers in 1951 were the Ajax mine (Golden Cycle Corporation), Cresson, United Gold Mines group (mine and dump ore), Strong (Front Range) mine, Tenderfoot-Mollie-Kathleen group, El Paso group (mine and dump ore), and Stratton Estate (Chicago Tunnel). About 24 other mines and dumps shipped some ore to the Carlton mill.

Georgia, North Carolina, and Tennessee Gold, Silver, Copper, Lead, and Zinc

(MINERAL REPORT)

By Robert W. Metcalf

GENERAL SUMMARY

PRODUCTION of copper and zinc in Tennessee was higher in 1951 than in 1950, whereas output of gold, silver, and lead in that State declined. Georgia produced a negligible quantity of gold, and North Carolina, which last produced any of the metals discussed in this chapter in 1949 (gold only), did not produce any of these metals. None of the other States in Region VII of the Bureau of Mines [1] have produced any of these metals since 1946.

The increased production of zinc and copper was due principally to an active operating year uninterrupted by major strikes. Contributing factors were augmented defense expenditures and an expanding level of business activity.

Data shown for output of recoverable copper in Tennessee include outputs for Pennsylvania and Vermont, to avoid disclosure of individual company operations. All tonnage figures reported herein are short tons and "dry weight"—that is, they do not include moisture. The prices for calculating the value of metal production are shown in table 1.

TABLE 1.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] (per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

[1] Price under authority of Gold Reserve Act of Jan. 31, 1934.
[2] Treasury buying price for newly mined silver July 1, 1946, to date—$0.9050505 ($0.905 used in 1947 for calculating purposes).
[3] Yearly average weighted price of all grades of primary metal sold by producers. Price in 1947 includes bonus payments by Office of Metals Reserve for overquota production.

[1] Region VII (Southeastern) of the Bureau of Mines is composed of the following States: Tennessee, North Carolina, South Carolina, Georgia, Alabama, Mississippi, and Florida.

Digitized by Google

Annual figures for the 5 years ended with 1951 and data showing the production of gold, silver, copper, lead, and zinc by months, in terms of recoverable metal, are given in tables 2 and 3.

TABLE 2.—Mine production of gold, silver, copper, lead, and zinc in Georgia and Tennessee in 1951, by months, in terms of recoverable metal [1]

Month	Gold [2] (fine ounces)	Silver [2] (fine ounces)	Copper [3] (short tons)	Lead [2] (short tons)	Zinc [2] (short tons)
January	9	2,080	1,249	----------	3,281
February	9	2,080	1,043	1	2,606
March	9	2,080	1,364	1	3,378
April	9	2,080	1,454	1	2,934
May	9	2,080	1,342	1	3,453
June	9	2,080	1,378	1	3,505
July	9	2,080	1,259	4	3,244
August	9	2,080	1,363	1	3,416
September	12	2,080	1,386	1	3,007
October	9	2,080	1,487	1	3,417
November	9	2,080	1,435	1	3,436
December	9	2,080	1,380	1	2,962
Total	111	24,960	16,140	14	38,639

[1] Mine production comprises ore, gravel, or other mineral material sold or treated and metal recovered as natural gold or as bullion from cyanidation or amalgamation and the estimated recoverable metal (or gross metal as indicated) contained in concentrates, ores, tailings, and other mineral materials shipped directly to smelters or sold to ore buyers within the year.
[2] All from Tennessee, except for 3 ounces of gold produced in Georgia in September. Data for Tennessee for gold and silver are estimated.
[3] Total for Pennsylvania, Tennessee, and Vermont; combined to avoid disclosing individual company operations.

TABLE 3.—Mine production of gold, silver, copper, lead, and zinc in Georgia, North Carolina, and Tennessee, 1947–51, in terms of recoverable metal [1]

Year	Mines producing		Crude ore sold or treated, (short tons)	Gold (lode)		Silver (lode)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1947	14	----------	2,149,010	379	$13,265	79,160	$71,640
1948	13	----------	2,165,202	175	6,125	39,695	35,926
1949	14	2	2,179,118	[2] 202	[2] 7,070	41,833	37,861
1950	12	----------	2,255,977	160	5,600	39,958	36,164
1951	14	----------	2,514,079	111	3,885	24,960	22,590

Year	Copper [1]		Lead		Zinc		Total value [1]
	Short tons	Value	Short tons	Value	Short tons	Value	
1947	13,686	$5,328,120	22	$6,336	31,212	$7,553,304	$12,972,665
1948	14,248	6,183,632	----------	----------	29,524	7,853,384	14,079,067
1949	13,449	5,298,906	257	81,212	29,788	7,387,424	12,812,473
1950	14,497	6,030,752	113	30,510	35,326	10,032,584	16,135,610
1951	16,140	7,811,760	14	4,844	38,639	14,064,596	21,907,675

[1] Data for copper in Pennsylvania and Vermont included with Tennessee to avoid disclosing individual company operations. The only production for North Carolina during the years shown here was 13 ounces of gold valued at $455 in 1949.
[2] Includes 27 ounces of placer gold valued at $945. No placer gold reported in other years shown.

Gold.—Most of the gold produced in southeastern United States is recovered as a byproduct from slimes in the electrolytic refining of copper. In 1951 production from Georgia and Tennessee in this region was 111 fine ounces compared with 160 ounces in 1950. One gold mine was operated in Georgia during 1951 and produced 3 fine ounces. The output of this mine constituted all the production from

Digitized by Google

gold ores in the region. No gold from placer operations was marketed during the year. As for many years, byproduct gold was obtained from copper ores from the Tennessee Copper Co. mines, Polk County, Tenn.

TABLE 4.—Mine production of gold in Southeastern region,[1] 1799–1951

State	Period	Fine ounces	Value
Alabama	1830–1951	49,495	$1,198,985
Georgia	1830–1951	870,663	18,089,052
North Carolina	1799–1951	1,164,601	24,328,298
South Carolina	1829–1951	318,801	7,562,125
Tennessee	1831–1951	21,863	512,835
Total	1799–1951	2,425,423	51,691,295

[1] Bureau of Mines, Region VII.

Silver.—All the silver produced in 1951 was recovered as a byproduct of copper ore mined in Tennessee. Silver recovered in this manner was 24,960 fine ounces, or 38 percent less than the 39,958 ounces reported in 1950.

Copper.—Output of copper in Pennsylvania and Vermont is included with that of Tennessee to avoid disclosure of individual company operations. Tennessee production was by the Tennessee Copper Co. (Pennsylvania and Vermont output was reported by Bethlehem Steel Co. and Vermont Copper Co., respectively). Combined output in Pennsylvania, Tennessee, and Vermont in 1951 totaled 16,140 short tons, an 11-percent increase over 1950. Copper production in each of these States in 1951 was somewhat larger than in 1950. The metal-mining industry in Tennessee was not seriously affected by labor strikes, and operation was virtually continuous during the year.

Lead.—A small quantity of lead ore was produced in 1951 by the Appalachian Zinc Co. from mines near Embreeville, Tenn. Small amounts of lead were recovered in 1951 as a byproduct of the smelting of zinc concentrates produced in Jefferson, Knox, and Polk Counties, Tenn. Lead output in 1951 totaled only 14 short tons compared with 113 tons in 1950.

Zinc.—Tennessee was the only State in the Bureau of Mines, Region VII, producing zinc. Production increased 9 percent in 1951 to 38,639 short tons compared with 35,326 tons in 1950. An extremely active year, virtually uninterrupted by strikes or work stoppages, contributed heavily to this rise in output. The leading producers in 1951 were The American Zinc Co. of Tennessee (operating the Mascot No. 2, Jarnagin, Grasselli, and Athletic mines), Universal Exploration Co., and The Tennessee Copper Co.

MINING AND METALLURGICAL INDUSTRY

Nearly all the ore (no tailings were reported as treated) in Tennessee was treated at concentration mills at or near the mines and shipped to smelters, refineries, or oxide plants. Of the total of 2,514,079 short tons of material mined in this State and Georgia, 2,513,847 tons was treated initially at a concentration mill, and 232 tons was shipped direct to smelters.

TABLE 5.—Mine production of gold, silver, copper, lead, and zinc in Georgia and Tennessee, in 1951, by States, in terms of recoverable metal

State	Mines producing (lode)	Ore (short tons)	Gold (lode)		Silver (lode)	
			Fine ounces	Value	Fine ounces	Value
Georgia	1	5	3	$105		
Tennessee	13	2,514,074	108	3,780	24,960	$22,590
Total	14	2,514,079	111	3,885	24,960	22,590

State	Copper		Lead		Zinc		Total value
	Short tons	Value	Short tons	Value	Short tons	Value	
Georgia							$105
Tennessee	[1] 16,140	[1] $7,811,760	14	$4,844	38,639	$14,064,596	[1] 21,907,570
Total	[1] 16,140	[1] 7,811,760	14	4,844	38,639	14,064,596	[1] 21,907,675

[1] Data for copper in Tennessee include output in Pennsylvania and Vermont to avoid disclosing individual company operations.

TABLE 6.—Mine production of gold, silver, copper, lead and zinc in Georgia and Tennessee in 1951, by class of ore, in terms of recoverable metal [1]

Class of ore	Number of mines	Material sold or treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)
Gold ore (Georgia)	1	5	3				
Copper ore (Tennessee)	5	1,144,923	108	24,960	[2] 16,140		[3] 38,639
Zinc ore (Tennessee)	7	1,369,128				10	
Lead ore (Tennessee)	1	23				4	
Total, all sources	14	2,514,079	111	24,960	[2] 16,140	14	38,639

[1] Definitions used in ore classification are given in the Gold and Silver chapter of this volume.
[2] Data for copper in Pennsylvania (from magnetite-pyrite-chalcopyrite ore) and Vermont included with Tennessee to avoid disclosing individual company operations.
[3] Zinc from Tennessee copper ore included with that from zinc ore to avoid disclosing individual company operations.

TABLE 7.—Mine production of gold, silver, copper, lead, and zinc in Georgia and Tennessee in 1951, by method of recovery and type of material processed, in terms of recoverable metal

Method of recovery and type of material processed [1]	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)
Amalgamation	3				
Concentration and smelting of concentrates	108	24,960	[2] 16,140	10	38,567
Direct smelting				4	72
Total	111	24,960	[2] 16,140	14	38,639

[1] All ore; no other lode material processed or placer recovery in 1951.
[2] Pennsylvania and Vermont production included with Tennessee to avoid disclosing individual operations.

Digitized by Google

The methods of treatment used in the mills and other operating details are given in the Review by States that follows.

Active smelters and refineries that treated primary materials produced in Tennessee include copper plants at Copperhill, Tenn., and Laurel Hill, N. Y.; a lead plant at Herculaneum, Mo.; and zinc plants at Fort Smith, Ark., Danville, East St. Louis, La Salle, and Depue, Ill.; Donora, Josephtown, New Castle, and Palmerton, Pa.; and Columbus, Ohio.

REVIEW BY STATES

GEORGIA

Gold has been mined intermittently in Georgia for many years. Production generally has been small. In 1951 the operation of one lode-gold mine was reported in Gwinnett County near Buford. A little over 3 ounces of gold was recovered.

NORTH CAROLINA

No production of gold, silver, copper, lead, or zinc has been reported from North Carolina since 1949, when small amounts of both lode and placer gold were recovered.

TENNESSEE

Copper and zinc output from Tennessee mines in 1951 rose 11 and 9 percent, respectively, compared with 1950. Gold, silver, and lead output decreased 33, 38, and 88 percent, respectively. Production was reported by 6 companies from 13 mines. Augmented metal output in 1951 was accompanied by an 11-percent increase in total tonnage of ore produced compared with 1950. Gold and silver are produced as byproducts of copper-zinc mining in Tennessee. These metals are virtually unassayable in the original ore and are allowed to accumulate in the copper smelter and the copper sulfate circuit, usually for several months, until there is enough to warrant casting high-gold-silver-copper anodes for shipment to an electrolytic refinery. Because of the practice of allowing gold and silver to accumulate for several months, the monthly and annual mine-production rates of these two metals are estimated. As in 1949 and 1950, lead was produced as a result of prospecting and exploration near Embreeville, Washington County, and not from regular mining. The decreased output of lead therefore was not significant.

The American Zinc Co. of Tennessee operated 3 mines in Jefferson County (Athletic or Mossy Creek, Grasselli, and Jarnagin) and 1 in Knox County (Mascot No. 2). All ore was beneficiated at the company mill at Mascot. Custom ore from the Universal Exploration Co. also was treated during 1951. Concentrates from this mill were shipped to five smelters or oxide plants. The American Zinc Co. reported the discovery of a large deposit of zinc ore in the same general area as its other mines, and a new mine was under development in this

Digitized by Google

area at the end of the year. Development at the mines of the American Zinc Co. of Tennessee included 4,287 feet of drift and 46,139 feet of diamond drilling at the Mascot No. 2; 413 feet of drift and 2,417 feet of diamond drilling at the Jarnagin; 2,262 feet of drift, 3,619 feet of diamond drilling, and 9,610 feet of churn drilling at the Grasselli; and 377 feet of drift at the Athletic.

The Tennessee Copper Co. operated five mines in Polk County throughout 1951—the Boyd, Burra Burra, Calloway, Mary, and Eureka. Development during the year included 1,430 feet of shaft, 13,719 feet of drifts, 4,967 feet of raises, and 15,674 feet of diamond drilling. Ore is initially beneficiated at the company London and Isabella flotation plants, which have a daily capacity of 3,200 tons. Copper, zinc, and iron concentrates were recovered by bulk flotation, followed by three stages of selective flotation. Zinc concentrates were shipped to smelters or oxide plants for further refining. Copper concentrates were converted to blister copper in the company 150-ton reverberatory furnace and cast chiefly as shot copper for the manufacture of copper sulfate.

In Jefferson County the Universal Exploration Co. operated the Davis-Bible group of mines. Ore was beneficiated in its 800-ton-per-day flotation mill. The company was reported to be expanding its mine and mill capacity at Jefferson City to 1,700 tons per day. Additional flotation capacity included sixteen 56-inch flotation machines. Mine development included 493 feet of shaft, 4,147 feet of drift, 18,581 feet of diamond drilling, and 2,063 feet of churn drilling. Most of the ore was treated at the company mill, but some ore was shipped to the Mascot mill of the American Zinc Co. of Tennessee.

The Appalachian Zinc Co. was reported to have shipped some zinc ore from near Embreeville. According to smelter returns, two other operators produced some zinc ore, including small shipments of carbonate ore from near Jefferson City. The Appalachian Mining & Smelting Co. had not yet begun active operations by the end of the year at its lead and zinc properties near Embreeville.

Small amounts of lead were recovered by the Athletic Mining & Smelting Co., Fort Smith, Ark., in smelting zinc concentrates produced by the Tennessee Copper Co. The Donora (Pa.) smelter of the American Steel & Wire Co. recovered small values in lead from zinc ores produced both by the American Zinc Co. of Tennessee and Universal Exploration Co. In addition, some lead ore was mined by the Appalachian Zinc Co. from the Embreeville area.

Idaho

Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By Philip B. Dettmer

GENERAL SUMMARY

COPPER was the only metal of the five nonferrous metals to show an increased output in 1951 (3 percent). This was due chiefly to the opening of the Blackbird-Chicago mine in Lemhi County by the Calera Mining Co., which added 295,000 pounds recoverable copper to the State copper total, as well as a substantial quantity of cobalt. Lead, zinc, silver, and gold—the principal metals mined in Idaho—each declined in 1951 output. Lead production dropped from 100,025 tons in 1950 to 76,713 tons in 1951, a decline of 23 percent; zinc from 87,890 tons in 1950 to 78,121 tons in 1951, a decline of 11 percent; silver from 16,095,019 ounces in 1950 to 14,748,188 ounces in 1951, a decline of 8 percent; and gold from 79,652 ounces in 1950 to 45,064, a decline of 43 percent.

The total value of the five metals produced in 1951 was $70,953,653, an increase of only 1 percent despite advances in market prices of copper, lead, and zinc. The total value of the gold output was $1,577,240, 2 percent of the State total value; silver $13,352,231 (19 percent); copper, $1,045,440 (2 percent); lead, $26,542,698 (37 percent); and zinc, $28,436,044 (40 percent). The State remained the largest producer of silver in the United States and was exceeded only by Missouri in lead production and by Montana in zinc output. About 92 percent of the State silver, 87 percent of the copper, 92 percent of the lead, and 96 percent of the zinc came from the Coeur d'Alene region of Shoshone County; the remaining silver, lead, and zinc came largely from the Warm Springs district of Blaine County, and the remaining copper from the Blackbird district of Lemhi County.

About 44 percent of the State gold output in 1951 came from the Yellow Pine mine in the Yellow Pine district, Valley County; the remainder came largely from a lode mine in the Middle Boise district, Elmore County, and dredging operations in the Yankee Fork district, Custer County, and the Boise Basin district, Boise County.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production reported herein has been calculated at the prices given in table 1.

[1] Includes all placer operations using power excavator and washing plant, both on dry land; an outfit with movable washing plant is termed a "dry-land dredge."
[2] A mine using more than one method of recovery is counted but once in arriving at total for all methods.

Gold.—The output of recoverable gold in Idaho in 1951 was 45,064, or 34,588 ounces less than in 1950, a decrease of 43 percent. This reverses the upward trend which began in 1946.

The sharp decline in gold output can be attributed partly to a 60 percent decline in gold production of the Bradley Mining Co. Yellow Pine mine in Valley County. The company reported that pit conditions made economic mining of ore difficult, resulting in a great variety of mill feed and poor metallurgical recovery. In addition to the decrease in Yellow Pine production, there was a drop of 8,044 ounces of gold in Idaho County output due primarily to the cessation of operations of the Wild Rose group of placers by the

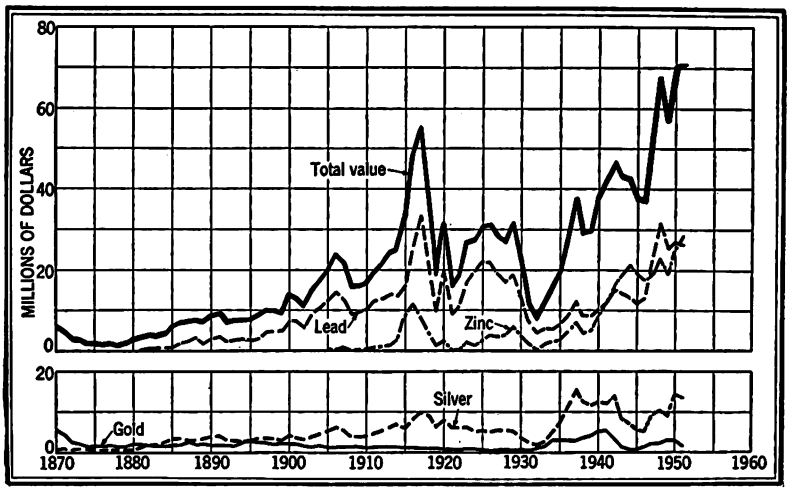

FIGURE 1.—Value of mine production of gold, silver, lead, and zinc, and total value of gold, silver, copper, lead, and zinc in Idaho, 1870–1951. The value of copper has been less than $2,000,000 annually, except in a few years.

Warren Dredging Co. A summer shortage of underground miners and a strike in late August and early September also contributed to the decreased production.

Gold produced from lode mines in 1951 was 33,214 fine ounces compared to 62,091 fine ounces in 1950, and that from placer properties was 11,850 fine ounces compared with 17,561 fine ounces. The Yellow Pine mine continued to be by far the largest producer of gold in Idaho; it was followed by the Boise-Rochester mine group at Atlanta operated by the Talache Mines Inc., a bucket-line dredge on the Yankee Fork placers property in Custer County operated by the Warren Dredging Co., and a bucket-line dredge at Idaho City operated by the Idaho-Canadian Dredging Co. Of the total gold produced in Idaho in 1951, nearly 64 percent came from gold ore, 24 percent from bucket-line dredging, 6 percent from zinc-lead ores, and 2 percent from dragline dredging. Four bucket-line dredges and 5 dragline dredges treated about 1,866,000 cubic yards of gravel in 1951 and recovered 11,603 fine ounces of gold and 4,789 fine ounces of silver.

Silver.—Idaho's output of recoverable silver in 1951 was 14,753,023 fine ounces, a decline of 1,341,996 ounces from the 1950 production. The State continued to be the largest producer of silver in the United States—a rank held since 1933. The Coeur d'Alene region produced 13,639,808 fine ounces of silver, or 92 percent of the State total silver output for 1951. This was 1,416,323 fine ounces less than the Region's 1950 output, the decline being caused by a summer shortage of underground personnel and the strike in late summer. Of the State total silver, silver ore yielded 66 percent, zinc-lead ore and old tailings 28 percent, lead ore 3 percent, and gold ore most of the remainder. The recovery of silver from silver ore increased 65,249 ounces in 1951, decreased 1,377,401 ounces from zinc-lead ores and 338,880 ounces from lead ores, and increased 4,781 ounces from gold ores. Nine

Digitized by Google

mines—the Sunshine, Polaris, Silver Summit, Bunker Hill, Silver Dollar group, Triumph, Page, Silver Syndicate, and Star mines produced 84 percent of the State total in 1951. Six properties (Sunshine, Polaris, Silver Dollar group, Silver Syndicate, Sunshine Consolidated, and Metropolitan, near Kellogg) operated by the Sunshine Mining Co. produced 7,990,034 ounces of silver in 1951, or 54 percent of the State total.

Copper.—The output of copper in Idaho in 1951 was 4,320,000 pounds, an advance of 106,000 pounds over the 1950 output. About 83 percent of the State copper output in 1951 was recovered as a byproduct in the treatment of zinc-lead ore and silver ore from mines in the Coeur d'Alene region and about 7 percent was recovered from copper concentrates produced by the newly opened Blackbird-Chicago mine operated by Calera Mining Co. in the Blackbird district of Lemhi County. The Sunshine mine near Kellogg in the Coeur d'Alene region continued to be the largest producer of copper in Idaho. It was followed by the Silver Summit, Polaris, Bunker Hill & Sullivan, and Silver Dollar properties.

Lead.—In 1951 the mines in Idaho produced 76,713 short tons of recoverable lead, 23,312 tons less than in 1950. The decline resulted principally from a shortage of underground miners in late summer and early fall and the strike in late August and early September. Ninety-two percent of the State total lead came from the Coeur d'Alene region; most of the remainder was produced in the Warm Springs district of Blaine County, Bayhorse district of Custer County, and the Texas district of Lemhi County. Zinc-lead ore and old tailings from the Coeur d'Alene region yielded 78 percent of the lead; and lead ore and silver ore from the same region accounted for over 11 percent of the 1951 State lead output.

The Bunker Hill & Sullivan mine at Kellogg was by far the largest producer of lead in Idaho in 1951, although its output was 33 percent less than in 1950. The combined lead output of the five largest

producing mines (each producing more than 6 million pounds of lead)—the Bunker Hill, Page, Star, Morning, and Triumph was 91,268,537 pounds, or 59 percent of the State total. Other important producers in 1951 were the Sidney group, Dayrock, Tamarack, Constitution, Sunshine, and Frisco group properties.

Zinc.—In 1951 the mines in Idaho produced 78,121 short tons of recoverable zinc, 9,769 tons less than the 1950 output or a decrease of 11 percent. About 96 percent of the State total zinc came from the Coeur d'Alene region and most of the remainder from the Triumph

Digitized by Google

mine in the Warm Springs district of Blaine County. Zinc-lead ore and old tailing concentrates yielded over 94 percent of the State total zinc; old zinc slag smelted and fumed, 5 percent; and lead ore, silver ore, and old lead tailings most of the remainder. The largest producer of zinc in the State in 1951 was the Star mine operated by the Sullivan Mining Co., with a production of 36,789,257 pounds of recoverable zinc, or 24 percent of the State total zinc. Nine other properties (each producing more than 5 million pounds of recoverable zinc)—the Bunker Hill, Page, Morning, Sidney Group, Bunker Hill smelter slag dump, Constitution, Tamarack, Monitor group, and Frisco group produced the bulk of the remaining output in 1951.

MINING INDUSTRY

Despite an appreciable advance in the price of copper, lead and zinc in 1951, gold output dropped 43 percent, silver 8, lead 23, and zinc 11. A shortage of underground miners in the late summer and early fall and a regional labor strike from late August to early September were the chief reasons for the decline in output of these metals. The drastic drop in gold output was due to pit conditions of the Yellow

[1] Detail will not necessarily add to totals because some mines produce more than one class of ore.

Digitized by Google

Pine mine, a major producer, which made economic mining of ore difficult and resulted in poor metallurgical recovery. Copper was the only metal that showed an increase in 1951 (3 percent). The opening of the Blackbird-Chicago mine near the town of Cobalt, Idaho, by the Calera Mining Co. added 295,000 pounds of recoverable copper to the State total copper.

About 93 percent of the zinc-lead ore and old tailings (by far the chief ore output of the State), 97 percent of the silver ore, 91 percent of the lead ore and old tailings, and 100 percent of the zinc ore and old zinc slag were produced in the Coeur d'Alene region. Placer mining activity in Idaho declined in 1951. Nine dredges (5 dragline and 4 bucket-line) recovered 11,603 fine ounces of gold in 1951 compared with 16 dredges (11 dragline, including 9 nonfloating washing plants, 4 bucket-line, and 1 suction) in 1950 that recovered 17,087 fine ounces of gold.

Definitions used in ore classification are given in the Gold and Silver chapter of this volume.

METALLURGICAL INDUSTRY

Of the 3,254,791 tons of ore produced in Idaho in 1951, 3,172,257 tons (97 percent) was treated at milling plants and the remainder—82,534 tons (3 percent)—was shipped crude to smelters.

Milling plants in 1951 treated principally zinc-lead ore and old tailings (2,068,612 tons), gold ore (638,271 tons), silver ore (272,915 tons), lead ore (88,220 tons), and zinc ore (150 tons). Current hot zinc slag totaling 136,928 tons was fumed, and 64,986 tons of old dump lead-smelter slag was delivered for smelting and fuming. Metals

recovered from the old dump slag were credited to the Bunker Hill smelter dump, and metals recovered from the hot slag were credited to various producers of the ores and concentrates that contributed during the year to the slag-making material.

The Bunker Hill & Sullivan Mining & Concentrating Co. operated its Bradley lead smelter and refinery on ore and concentrates, chiefly from mines and mills in the Coeur d'Alene region; both plants were closed on July 20 and from August 27 to September 6 owing to a strike, making a total of 12 days lost.

According to the Bunker Hill & Sullivan Mining & Concentrating Co.'s annual stockholders' report for 1951, continuous lead softening had been firmly established at Bunker Hill and was satisfactory. Construction of a new crushing and fine grinding plant was nearing completion. The company also operated its antimony and cadmium plants, 2,000-ton flotation mill (including a sink-and-float unit), 300-ton tailing-treatment plant for recovery of silver, iron, lead, and zinc from old jig tailings, and the 450-ton zinc slag-fuming plant at

Bradley. The annual stockholders' report disclosed that the smelter produced 3,283 ounces of gold, 10,147,635 ounces of silver, 149,546 pounds of cadmium, 1,174 tons of copper, 723 tons of antimony, 13,372 tons of zinc, and 54,315 tons of lead. The Sullivan Mining Co. operated its 150-ton electrolytic zinc plant near Bradley, producing 54,468 tons of high-grade slab zinc and 272 tons of electrolytic cadmium. In addition, the plant recovered from residues and other byproducts, 8,480 tons of zinc, 3,441 tons of lead, 160 tons of copper, 515,660 ounces of silver, and 1,929 ounces of gold.

The Bradley Mining Co. operated its 2,200-ton flotation mill and antimony-gold smelter at Stibnite, Valley County, but reported that pit conditions resulted in a varied mill feed and a poor metallurgical recovery.

REVIEW BY COUNTIES

BLAINE

Warm Springs District.—The Triumph Mining Co.'s North Star mine in the Warm Springs district increased its production of zinc-lead ore 70 percent from 44,846 tons in 1950 to 76,176 tons in 1951. This gain resulted from opening in February the company's new mill, which replaced the plant destroyed by fire in 1947.

Since the company's mining capacity was 200 tons of ore per day, the mill, during much of the year, used dump material mixed with mine ore. It was planned to increase mining activity in 1952 to meet mill requirements. Ore treated in 1951 yielded 553 ounces of gold, 493,641 ounces of silver, 76,518 pounds of copper, 6,045,438 pounds of lead, and 3,571,700 pounds of zinc. This constituted 85 percent of the total ore production from Blaine County for 1951.

The New Hope mine worked by Sun Valley Lead-Silver Mines Co., Ketchum, Idaho, although reported to be only in the development stage, nevertheless, ranked second to the Triumph North Star mine in zinc and lead production in Blaine County. A total of 161 tons of zinc and lead concentrates was produced, which contained 9 ounces of gold, 5,951 ounces of silver, 1,166 pounds of copper, 78,890 pounds of lead, and 59,048 pounds of zinc. Tailings from the North Star mine milled by the United States Smelting, Refining & Milling Co., Utah, produced concentrates containing 20 ounces of gold, 4,815 ounces of silver, 1,685 pounds of copper, 33,125 pounds of lead and 66,082 pounds of zinc.

BOISE

The principal producer in Boise County continued to be the Idaho-Canadian Dredging Co., which operated its 6-cubic-foot bucket-line dredge on Moores Creek near Idaho City, Boise Basin district, from January to July 31, 1951. A total of 720,000 cubic yards of material was treated which yielded 4,914 ounces of gold and 1,231 fine ounces of silver.

BONNER

The Hope mine owned by the Hope Silver Lead Mines, Inc., and worked throughout 1951 by lessees, was the largest producer in the Clark Fork district, with an output of 201 tons of lead milling ore, 51 tons of zinc-lead smelting ore, and 7 tons of lead smelting ore, all of which yielded 969 ounces of silver, 313 pounds of copper, 79,739 pounds of lead, and 8,038 pounds of zinc. The Whitedelf mine produced 654 tons of lead milling ore which yielded 60,861 pounds of lead and 4,656 ounces of silver. The Weber mine in the Lakeview district was worked from July to October 1951. A total of 7,893 tons of silver ore containing 72,854 ounces of recoverable silver was produced. Output from the Keep Cool mine, operated by the Idaho Lakeview Mines, totaled 750 tons of zinc-lead ore compared with 7 tons of silver ore in 1950.

BOUNDARY

Various lessees operated the Idaho-Continental mine in the Port Hill district and shipped a total of 1,211 tons of lead ore during the year.

[1] Includes Bonneville, Boundary, Butte, Cassia, Clark, and Clearwater Counties for which Bureau of Mines is not at liberty to publish separate figures.

Digitized by Google

CASSIA

Mining activity in Cassia County was confined to the Virginia group of mines, operated from March to December, 1951, by the Duvall Co. A new classifier, agitator tank, and storage tank were added during the year to the company's 225-ton cyanide plant.

CUSTER

The 1951 increase in the prices of copper, lead, and zinc resulted in a minor boom to Custer County, which recorded a 68 percent increase in overall value of the 5 metals as compared with 1950. The output of silver advanced 24 percent; copper, 63 percent; lead, 23 percent; and zinc 133 percent. The output of gold dropped 51 percent which was due primarily to decreased production at the Lucky Boy mine in the Yankee Fork district.

The Clayton mine in Bayhorse district, owned by the Clayton Silver Mines, produced 43 percent of the County ore output, making it the largest producer in Custer County. A total of 23,562 tons of zinc-lead ore milled in the company's 100-ton flotation mill yielded concentrates containing 42 ounces of gold, 116,688 ounces of silver, 20,932 pounds of copper, 2,277,050 pounds of lead, and 1,310,195 pounds of zinc.

Alder Creek District.—Principal district output in 1951 comprised lead smelting ore from the Champion mine operated by David Bell and the Homestake property owned by White Knob Mining Co.

Bayhorse District.—The principal output of the Bayhorse district was zinc-lead ore from the Clayton mine. The Red Bird mine, owned and operated by Buchman, Brecken, and Norden, shipped 3,930 tons of lead smelting ore, containing 16 ounces of gold, 42,483 ounces of silver, 1,203 pounds of copper, and 947,766 pounds of lead. The Bayhorse Mines, Inc., began working the McGregor mines in April. Activity was confined principally to construction of a 100-ton gravity and flotation mill and experimentation with mining methods.

Boulder District.—The Idaho-Custer Mines Co., Wallace, Idaho, bought all the assets of the Livingston Mines Inc. in 1951 and milled zinc-lead tailings from the Livingston mine located 16 miles south of Clayton, Idaho. This comprised the total output of the district. A total of 598 tons of lead concentrates and 586 tons of zinc concentrates was produced.

Seafoam (Greyhound) District.—The Mountain King mine worked by Fred and Earl Shirts was the only producing property in the district in 1951. A total of 660 tons of zinc-lead ore was shipped to a concentrating mill in Utah.

Yankee Fork District.—The major output of the Yankee Fork district was placer gold recovered by the Warren Dredging Corp. which operated a bucket-line dredge on the Yankee Fork placer. This property produced a total of 5,129 ounces of gold and 3,308 ounces of silver.

ELMORE

The Talache Mines, Inc., operated its Boise-Rochester group of claims 1 mile east of Atlanta, Idaho, in the Middle Boise (Atlanta) district, throughout the year and milled 8,973 tons of gold ore, which

Digitized by Google

was concentrated and amalgamated in its 400-ton amalgamation and concentration mill. A total of 6,301 ounces of gold and 37,367 ounces of silver was recovered.

IDAHO

The total value of gold and silver output from placer mines in Idaho County declined 83 percent in 1951. Gold output from bucket-line dredging dropped 92 percent, drag-line dredging, 49 percent, and hydraulic operations, 69 percent; whereas production by small-scale hand methods advanced 78 percent. Lode production fell off 15 percent from the 1950 figure.

LEMHI

Substantial increases in the production of copper and zinc were recorded in Lemhi County in 1951. Copper output advanced to nearly 4 times the 1950 output and zinc output to over 9 times the 1950 output. Silver production increased about 29 percent while that of gold and lead remained approximately the same.

The increase in copper output came primarily from the Blackbird-Chicago mine, owned and operated by the Blackbird Division of the Calera Mining Co., a subsidiary of Howe Sound Co. The property, a cobalt-copper producer, is located 9 miles from Cobalt, Idaho, in the primitive area of the Salmon National Forest. The 1,000-ton-per-day concentration mill was started in June 1951 on a 1-shift-per-day basis and treated dump material mixed with minor amounts of development ore from the Chicago ore zone. A total of 761 tons of copper concentrate containing 101 ounces of gold, 106 ounces of silver, and 302,107 pounds of copper was produced. Some cobalt was recovered but not shipped in 1951. This mine was expected to be one of Idaho's major copper producers in 1952.

Zinc output in Lemhi County increased largely as a result of expanded production at the United-Idaho mine located in the Texas district and operated by the United-Idaho Mining Co.

The Texas district contributed 55 percent of the total value of gold, silver, copper, lead, and zinc produced in the County in 1951. The principal producers in the Texas district were the Hill Top mine operated by Joe Hamilton and the United-Idaho property.

SHOSHONE (COEUR D'ALENE REGION)

Output of gold, silver, copper, lead, and zinc in Shoshone County in 1951 decreased from the 1950 level. Production of gold dropped 21 percent; silver, 9 percent; copper, 1 percent; lead, 25 percent; and zinc, 13 percent. Due to advances in the market prices of copper, lead, and zinc in 1951 the value of the metal output of the region showed an increase of $502,940. Shoshone County continued to contribute 92 percent of the output of Idaho in terms of dollar value of gold, silver, copper, lead, and zinc. The region remained the largest silver producing area in the United States and second in lead and zinc; it produced 92 percent of Idaho's silver in 1951, 87 percent of the copper, 92 percent of the lead, and 96 percent of the zinc. The zinc output of the region exceeded that of lead by 8,838,000 pounds or 6 percent.

Digitized by Google

Of the total material (2,393,939 tons) produced in 1951 in the Coeur d'Alene region, 80 percent was zinc-lead ore and old tailings, 11 percent silver ore, and 3.5 percent lead ore. The chief zinc-producing properties, according to rank, were the Star, Bunker Hill, Page, Morning, Sidney group, Bunker Hill smelter slag dump, Constitution, and Tamarack mines. The chief silver-producing properties, according to rank, were the Sunshine (including the Chester Vein), Polaris, Silver Summit, Bunker Hill, and Silver Dollar group of mines. The chief producers of lead, according to rank, were, Bunker Hill, Page, Star, and Morning mines.

Beaver District.—Seven mines in the Beaver district produced 80,190 tons of zinc-lead ore. The largest producer in the district was the Monitor group (Carlisle, Interstate, Silver Tip, Amazon) worked by the Day Mines, Inc., throughout 1951. The zinc-lead ore was treated in the Carlisle 300-ton flotation mill near Wallace. Zinc production from the Monitor group increased considerably in 1951 owing to steady mining of the Amazon vein. The Blue Grouse property owned by Day Mines, Inc., was worked intermittently by Roy Smith, essee; the output was zinc-lead ore, which was treated at the Rex mill, Wallace. The Interstate Callahan property, as well as the Interstate dump, also owned by Day Mines, Inc., was worked intermittently by Zanetti Bros., and the zinc-lead ore produced was treated in the Rex mill operated by Zanetti Bros. Lessees worked the Parrott mine and shipped zinc-lead ore to the Rex mill for milling. The Sunset Lease (a partnership in which Day Mines, Inc., has a 70 percent interest with the Anaconda Copper Mining Co.) was operated the entire year by Korsage Bros. and Zanetti Bros., with some of the ore being treated in the Golconda Custom mill and the remainder in the Rex mill.

Evolution District.—Silver ore was the principal ouput of the Evolution district, with the Sunshine Mining Co. being the major producer. A total of 116,324 tons of silver ore from the Sunshine mine (including the Chester Vein) was treated in the company's 1,350-ton flotation mill, which yielded 125 ounces of gold, 4,106,777 ounces of silver, 1,017,553 pounds of copper, 3,403,888 pounds of lead, and 352,236 pounds of zinc. In addition to ores from the Sunshine mine, the mill treated the output of the Polaris Mining Co., Silver Syndicate, Inc., Silver Dollar Mining Co., Sunshine Consolidated, Inc., Metropolitan Mines Corp. and the Big Creek Apex Mining Co.

The Big Creek tailings deposit along the South Fork of the Coeur d'Alene river, the DeBlock tailings at the mouth of Lake Gulch, and the Osburn tailings deposits were worked by Zanetti Bros. and trucked to the company's tailings mill in Osburn.

The only copper ore produced in the district came from the Coeur d'Alene Mines Corp. Mineral Point mine. A total of 7,682 tons of ore was milled in the company's 600-ton flotation mill and yielded 45 ounces of gold, 79,851 ounces of silver, 44,408 pounds of copper, and 537 pounds of lead.

Hunter District (Mullan).—The Star mine of the Sullivan Mining Co. was the major producer of the Hunter district and in 1951 ranked first in zinc production and third in lead in the State. A total of 265,724 tons of zinc-lead ore was produced from this mine, which was

Digitized by Google

treated in the company's 1,000-ton flotation mill and yielded 9,787 tons of lead concentrates and 36,798 tons of zinc concentrates which together contained 180 ounces of gold, 227,073 ounces of silver, 124,394 pounds of copper, 15,608,945 pounds of lead, and 38,545,792 pounds of zinc.

Production from the Morning mine, owned and operated by the Federal Mining & Smelting Co., declined in 1951 as compared with 1950. A total of 88,817 tons of zinc-lead ore was treated in the company's 1,200-ton flotation mill and yielded 18,602 tons of concentrates containing 72 ounces of gold, 153,945 ounces of silver, 103,452 pounds of copper, 9,874,966 pounds of lead, and 14,422,558 pounds of zinc.

The Lucky Friday Silver-Lead Mines Co. worked the Lucky Friday mine during 1951 and shipped zinc-lead ore to the Golconda custom flotation mill in Wallace. Lead and zinc concentrates amounting to 1,431 and 174 tons, respectively, were produced from this ore and together contained 132 ounces of gold, 208,442 ounces of silver, 60,480 pounds of copper, 1,824,238 pounds of lead, and 413,154 pounds of zinc. Other important producing properties in the district included the Golconda, Hickory, and West Mammoth.

Lelande District (Burke, Mace, Frisco).—The Frisco group (Black Bear and Gem Veins) owned and operated by the Federal Mining & Smelting Co. was the largest producer in the Lelande district; 52,100 tons of zinc-lead ore containing 48 ounces of gold, 56,712 ounces of silver, 71,479 pounds of copper, 3,496,000 pounds of lead, and 6,214,200 pounds of zinc was shipped to the Morning mill for treatment. The upper levels of the Frisco mine were worked by the Hull lease; 28,441 tons of zinc-lead ore containing 22 ounces of gold, 9,962 ounces of silver, approximately 16,250 pounds of copper, 463,392 pounds of lead, and 4,300,840 pounds of zinc was milled in the Hull lease 90-ton flotation mill.

Day Mines, Inc., worked its Hercules mine and shipped zinc-lead ore to the Sherman mill for treatment. The Sherman mine and 300-ton flotation mill, also owned by Day Mines, Inc., recorded a drop in production of lead ore, its principal product. The remainder of the district output was chiefly zinc-lead ore from 13 other properties.

Placer Center District.—The Tamarack mine, owned and operated by the Day Mines, Inc., had the largest output in the district in 1951. The property was worked throughout the year and the zinc-lead ore was treated in the Tamarack 400-ton flotation mill at Dorn. The Day Mines, Inc., also operated its Dayrock, Option, Black Cloud, California, and Pan Handle groups, treating the lead ore in its 250-ton bulk flotation mill at Bunn. The Success group was worked throughout the year by lessee Wylie Gardner, and the zinc-lead ore produced was treated in the Rex Mill. The remaining district output consisted of lead ore from the Galena mine, lead tailings from the Rex tailings dump, and zinc-lead ore from Tamarack No. 5 mine.

Yreka District (Kellogg).—Mine output in Yreka district dropped appreciably in 1951 owing primarily to a shortage of underground

802512—54——95

Digitized by Google

mine labor during the late summer months and early fall and a loss of productive time during a strike from August 27 to September 6. Ore production for the district in 1951 declined about 1 percent; gold, 24 percent; silver, 31 percent; copper, 26 percent; lead, 28 percent; and zinc, 13 percent. Despite price increases of copper, lead, and zinc in 1951, the total value of district metal output was $29,569,513, a decrease of 3 percent from the 1950 figure. The district remained by far the largest lead and zinc producing area in Idaho and ranked second in silver output.

The Bunker Hill & Sullivan mine at Kellogg continued to be the largest producer of ore in the district, as well as the largest producer of lead in Idaho. Output in 1951, according to the annual report to stockholders, totaled 1,703,121 ounces of silver, 22,478 tons of lead, and 10,298 tons of zinc in terms of gross metal content of concentrates. Zinc output in 1951 was 19 percent greater than in 1950, making the Bunker Hill & Sullivan mine the second largest producer of zinc in Idaho in 1951. The silver and lead output in 1951 decreased 36 percent and 33 percent, respectively, from the 1950 level.

John George continued leasing operations in the upper levels of the Bunker Hill & Sullivan mine and treated about 15,000 tons of lead ore in his 250-ton concentrator, producing lead concentrates containing 27,794 ounces of silver, 695 tons of lead, and 172 tons of zinc.

Production of the Page mine of the Federal Mining & Smelting Co. during 1951 was appreciably less than in 1950 as a result of the shortage of miners during the summer months and the strike in late August and early September. A total of 130,181 tons of zinc-lead ore was treated in the company's 500-ton flotation mill, a decrease of 18 percent from 1950 output. Silver production of the Page mine decreased 12 percent in 1951, lead 22 percent, and zinc 20 percent.

The Highland Surprise Consolidated Mining Co. operated its Highland Surprise mine on Stewart Creek throughout the year and reported the production of 25,100 tons of zinc-lead ore which, when treated in the company's 300-ton flotation mill, yielded concentrates containing a total of 64 ounces of gold, 16,314 ounces of silver, 11,200 pounds of copper, 1,033,015 pounds of lead, and 1,895,447 pounds of zinc in terms of recoverable metal. Sunset Minerals, Inc. worked the Liberal King mine during 1951 and produced 117 ounces of gold, 20,711 ounces of silver, 17,044 pounds of copper, 1,492,647 pounds of lead, and 3,223,986 pounds of zinc as recoverable metal. The Sidney Mining Co. operated its Sidney group and 300-ton flotation mill on Denver Creek near Kellogg throughout 1951 and produced 4,145 tons of lead concentrates and 10,347 tons of zinc concentrates, which together contained 125 ounces of gold, 115,763 ounces of silver, 33,836 pounds of copper, 5,596,205 pounds of lead, and 11,209,347 pounds of zinc as recoverable metal. From the Constitution mine, the Spokane-Idaho Mining Co. produced a total of 2,018 tons of lead concentrates and 8,072 tons of zinc concentrates, which together yielded 142 ounces of gold, 102,607 ounces of silver, 32,876 pounds of copper, 3,439,948 pounds of lead, and 7,983,859 pounds of zinc.

Digitized by Google

VALLEY

The Bradley Mining Co. worked its Yellow Pine mine in the Yellow Pine district throughout the year and produced 620,733 tons of gold-antimony ore which, when concentrated in the company's 2,200-ton flotation mill, yielded 14,394 tons of gold concentrate containing 19,605 ounces of gold and 141,044 ounces of silver. Compared with the 1950 production, this was a decrease of 60 percent in the gold output and an increase of 3 percent in the silver output. Nevertheless, the Yellow Pine property produced 59 percent of the State total gold in 1951.

TABLE 11.—Mine production of gold, silver, copper, lead, and zinc in the Coeur d'Alene region, Shoshone County, 1947–51, and total 1884–1951, in terms of recoverable metal

Year	Mines producing		Material sold or treated (short tons)	Gold, lode and placer (fine ounces)	Silver, lode and placer (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)	Total value
	Lode	Placer

Illinois, Kentucky, Maryland, New Jersey, New York, Pennsylvania, Vermont, and Virginia

Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By Samuel A. Gustavson

GENERAL SUMMARY

EACH of the States discussed in this chapter is a producer of one or more of the five metals—gold, silver, copper, lead, and zinc—within Region VIII of the Bureau of Mines. States in the area not producing these metals are: Connecticut, Delaware, Indiana, Maine, Massachusetts, New Hampshire, Ohio, Rhode Island, and West Virginia. Data for previous years will be found in earlier Minerals Yearbooks in chapters entitled "East of the Mississippi River" or "Eastern and Central States."

Production generally increased in 1951, except for Northern Illinois and Virginia. In Northern Illinois the Eagle-Picher Co., Mining and Smelting Division, operated steadily, but production was only about half that in 1950; and in Virginia a strike stopped production at the Austinville mine of the New Jersey Zinc Co. from April 1 to October 1. Both companies produce lead and zinc.

The value of the metal production reported herein, except that of zinc in New Jersey, has been calculated at the prices shown in table 1. The value of the New Jersey output is the total value of the zinc recoverable as metal and oxide after freight, haulage, smelting, and manufacturing charges are added.

TABLE 1.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] (per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

[1] Price under authority of Gold Reserve Act of Jan. 31, 1934.
[2] Treasury buying price for newly mined silver, July 1, 1946, to date—$0.9050505 ($0.905 used in 1947 for calculating purposes).
[3] Yearly average weighted price of all grades of primary metal sold by producers. Price in 1947 includes bonus payments by Office of Metals Reserve for overquota production.

TABLE 2.—Mine production of gold, silver, copper, lead, and zinc in Illinois, Kentucky, Maryland, New Jersey, New York, Pennsylvania, Vermont, and Virginia, 1947–51, in terms of recoverable metal [1]

Year	Mines producing	Material sold or treated (short tons)	Gold (lode)		Silver (lode)	
			Fine ounces	Value	Fine ounces	Value
1947	43	[2] 1,927,283	1,618	$56,630	55,531	$50,255
1948	45	[2] 2,051,754	2,304	80,640	61,476	55,639
1949	50	3,729,047	1,765	61,775	59,779	54,103
1950	34	4,305,103	1,930	67,550	73,397	66,428
1951	32	4,381,042	2,336	81,760	105,908	95,852

Year	Copper [1]		Lead		Zinc		Total value [3]
	Short tons	Value	Short tons	Value	Short tons	Value	
1947	12,691	$5,330,220	7,838	$2,257,344	138,356	$32,299,422	$39,993,871
1948	14,248	6,183,632	9,845	3,524,510	140,399	37,751,671	47,596,092
1949	13,449	5,298,906	8,641	2,730,556	121,215	31,860,350	40,005,690
1950	14,497	6,030,752	7,533	2,033,910	133,459	39,532,757	47,731,397
1951	16,140	7,811,760	6,275	2,171,150	135,533	50,711,969	60,872,491

[1] Data for copper production represent combined output of Vermont, Virginia (1947 only), Pennsylvania, and Tennessee; last State included to avoid disclosing individual company operations.
[2] Excludes magnetite-pyrite-chalcopyrite ore from Pennsylvania.
[3] Includes value of copper from Tennessee; *see* footnote 1.

TABLE 3.—Mine production of gold, silver, copper, lead, and zinc in Illinois, Kentucky, Maryland, New Jersey, New York, Pennsylvania, Vermont, and Virginia, in 1951, by States, in terms of recoverable metal

State	Mines producing	Material sold or treated (short tons)	Gold		Silver	
			Fine ounces	Value	Fine ounces	Value
Illinois	19	[1] 857,212			3,465	$3,136
Kentucky	5	[1] 66,119				
Maryland	1	1	1	$35		
New Jersey	2	404,424				
New York	2	500,490			47,568	43,051
Pennsylvania	1	2,083,658	2,179	76,265	13,575	12,286
Vermont	1	230,050	156	5,460	41,300	37,379
Virginia	1	239,088				
Total	32	4,381,042	2,336	81,760	105,908	95,852

State	Copper		Lead		Zinc		Total value
	Short tons	Value	Short tons	Value	Short tons	Value	
Illinois			3,160	$1,093,360	21,776	$7,926,464	$9,022,960
Kentucky			107	37,022	3,457	1,258,348	1,295,370
Maryland							35
New Jersey					62,917	[2] 24,279,745	[2] 24,279,745
New York			1,500	519,000	40,051	14,578,564	15,140,615
Pennsylvania	[3] 16,140	[3] $7,811,760					[4] 7,900,311
Vermont							[5] 42,839
Virginia			1,508	521,768	7,332	2,668,848	3,190,616
Total	[3] 16,140	[3] 7,811,760	6,275	2,171,150	135,533	50,711,969	[6] 60,872,491

[1] Includes fluorspar ore from which lead and/or zinc are recovered—Illinois 332,028 tons, Kentucky 45,478 tons.
[2] Estimated smelting value of recoverable zinc content of ore after freight, haulage, smelting, and manufacturing charges are added.
[3] Tennessee production and value included, to avoid disclosing individual company operations.
[4] Includes value of copper from Tennessee and Vermont; *see* footnote 3.
[5] Excludes value of copper, which is included under Pennsylvania; *see* footnote 3.
[6] Includes value of copper produced in Tennessee; *see* footnote 3.

METALLURGICAL INDUSTRY

During 1951 virtually all ore from the States reported in this chapter was treated in concentration mills at or near the mines and the product then shipped to smelters, refineries, or oxide plants. A total of 4,381,042 short tons of material was so treated, including 2,083,658 tons of magnetite-pyrite-chalcopyrite ore produced in Pennsylvania. This is also reported in the Iron Ore chapter of this volume. Fluorspar ore from all Southern Illinois mines and all Kentucky mines except the Hutson mine of Alcoa Mining Co. (*see* footnote 1, table 3) is duplicated in the Fluorspar chapter. In 1950, 4,305,103 tons of material was concentrated. About 1 ton of gold ore in 1951 and about 55 tons in 1950 were treated by amalgamation.

The methods of treatment used in some mills and other operating details are given in the Review by States that follows.

REVIEW BY STATES

ILLINOIS

Northern Illinois.—During 1951 five mines operated in Jo Daviess County. Production totaled 525,184 tons of crude ore, from which 28,539 tons of zinc concentrates containing 15,649 tons of recoverable zinc and 1,076 tons of lead concentrates containing 751 tons of recoverable lead were obtained. Tri-State Zinc, Inc., operated its Bautsch mine throughout the year and the Black Jack mine intermittently. The ore is concentrated in the company 850-ton jig and flotation mill. Output was slightly less than in 1950. The Eagle-Picher Co., Mining and Smelting Division (formerly the Eagle-Picher Mining & Smelting Co.), operated the Graham, Snyder, and Spillane mines and the 75-ton-per-hour jig and flotation mill throughout the year; output, however, was only about half that of 1950.

Southern Illinois.—Production of silver, lead, and zinc, virtually all from fluorspar mines, totaled 3,465 ounces of silver, 2,409 tons of lead, and 6,127 tons of zinc, an increase of 73, 65, and 4 percent, respectively, over 1950. Major reasons for the increases were a strong demand for fluorspar and higher prices for lead and zinc. The chief producers were the Ozark-Mahoning Co., Minerva Oil Co., Alcoa Mining Co., Crystal Fluorspar Co., and Rosiclare Lead & Fluorspar Mining Co.

KENTUCKY

A fivefold increase in zinc output from Kentucky mines in 1951 is attributable chiefly to the first full year's operation of the Alcoa Mining Co. Hutson zinc mine in Livingston County. The rest of the State output of zinc and all the lead were recovered as byproducts of fluorspar mining by the Ozark-Mahoning Co. and the United States Steel Co. (formerly United States Coal & Coke Co.), operating in Crittenden County; and the Inland Steel Co., operating in Livingston County.

MARYLAND

Philadelphia Mint receipts credited production of 1 ounce of gold from the Maryland mine in Montgomery County.

Digitized by Google

NEW JERSEY

The Franklin and Sterling Hill mines of the New Jersey Zinc Co. in Sussex County operated continuously thoughout the year, recording a zinc-production increase of 14 percent, in quantity and 41 percent in value over 1950. In 1950 the mines were idle from January 1 to January 26.

NEW YORK

In Lawrence County the St. Joseph Lead Co. operated the Balmat and Edwards mines nearly continuously throughout the year. Silver, lead, and zinc are produced from the Balmat mine and zinc from the Edwards mine. The State production of silver, lead, and zinc was greater in 1951, in spite of the loss of production from the Universal Exploration Co. Hyatt mine, which closed in May 1950.

PENNSYLVANIA

All the gold, silver, and copper produced in Pennsylvania for several years has been from the Cornwall mine of the Bethlehem Steel Co. in Lebanon County. Operation was continuous in 1951, and production of gold, silver, and copper increased 24, 29, and 28 percent, respectively, over 1950. The ore mineral is magnetite-pyrite-chalcopyrite.

According to the company's annual report, the New Jersey Zinc Co. had sunk the shaft at its zinc mine near Friedensville to within 175 feet of the objective depth of 1,260 feet.

VERMONT

Vermont has only one active producer of the metals discussed in this chapter. The chief product is copper, with gold and silver as relatively minor coproducts. Mining was carried on at a steady rate throughout 1951. In terms of recoverable metal, copper production was about 8 percent greater than in 1950 and gold and silver output 7 and 46 percent greater, respectively. An exploration contract between the Vermont Copper Co. and the Defense Minerals Exploration Administration for search for additional copper ore in Orange County was approved in August. The contract specified an expenditure of $51,382, the Government and the company each to furnish half.

VIRGINIA

Output of lead and zinc was 54 and 41 percent less, respectively, in 1951 than in 1950. A strike at the Austinville mine of the New Jersey Zinc Co. in Wythe County, which stopped production from April 1 to October 1, was the chief reason for the decrease.

No production was reported by the Timberville Mining Co. in Frederick County. The New Jersey Zinc Co. reported the starting of shaft-sinking operations preparatory to development of its property at Ivanhoe, Va., near Austinville. The ore from this property will be concentrated at Austinville.

Michigan and Wisconsin
Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By Samuel A. Gustavson

GENERAL SUMMARY

COPPER is currently produced in the Upper Peninsula of Michigan in Houghton and Keweenaw Counties from amygdaloid and conglomerate lode deposits and from re-treatment of old mill tailings. In 1951 production of copper (24,979 tons) was 2½ percent less than in 1950. During 1951 an estimated $568,193 in exploration contracts covering search for copper ore in Houghton and Keweenaw Counties was approved by the Defense Minerals Exploration Administration (DMEA), formerly part of the Defense Minerals Administration (DMA). The Government share of the cost was $284,096. Government price assistance was afforded several high-cost copper mines through agreements between companies and the Defense Materials Procurement Agency (DMPA), formerly DMA, which guaranteed with certain limitations floor prices ranging from 25.5 to 33.8 cents per pound. On November 15, 1951, the Reconstruction Finance Corporation (RFC) approved a $57,185,000 loan for developing the White Pine Copper deposit in Ontonagon County. Limited production is planned for the middle of 1954.

Zinc and lead are produced in the southwestern portion of Wisconsin in Grant, Iowa, and Lafayette Counties. Output of both metals in 1951—1,391 tons of lead and 15,754 tons of zinc—was over 2½ times that of 1950. Higher metal prices and/or Government assistance enabled new operators to start producing and stimulated increased output from others. Through DMPA a development loan of $80,000 was authorized in September 1951 to the Miffiin Mining Co., and at the year end DMEA had approved exploration contracts totaling $329,203.13.

There has been no production of gold in either Michigan or Wisconsin in recent years. Silver production was last reported in Michigan in 1947.

In this report all tonnage figures are short tons and "dry weight"; that is, they do not include mositure. The values have been calculated at the prices shown in table 1.

December	2,419	162	1,810
Total	24,979	1,391	15,754

METALLURGICAL INDUSTRY

All the ore and old tailings produced in Michigan and Wisconsin were treated at concentrating mills at or near the mines, and then shipped to smelters or oxide plants. In Michigan, the Calumet & Hecla Consolidated Copper Co. shipped all of its copper concentrates to the company smelter at Hubbell. Copper Range Co. and Quincy Mining Co. copper concentrates were processed in the Quincy smelter at Hancock. Wisconsin lead and zinc concentrates were sold to American Smelting & Refining Co., American Zinc Co. of Illinois, Matthiessen & Hegeler Zinc Co., and New Jersey Zinc Co.

Definitions used in ore classification are given in the Gold and Silver chapter of this volume. Table 3 presents data concerning types of ores and concentrates produced in Michigan and Wisconsin.

TABLE 3.—Mine production of copper, lead, and zinc in Michigan and Wisconsin in 1951, by method of recovery and class of material processed, in terms of recoverable metal, in short tons[1]

	Material treated	Concentrate shipped to smelters and recoverable metal			
		Concentrate	Copper	Lead	Zinc
BY STATE					
Michigan	4,471,334	40,272	24,979		
Wisconsin	514,721	29,877		1,391	15,754
BY CLASS OF MATERIAL TREATED					
Copper (Michigan)	4,471,334	40,272	24,979		
Zinc (Wisconsin)	50,615	4,011		50	2,110
Zinc-lead (Wisconsin)	464,106	25,866		1,341	13,644
BY CLASS OF CONCENTRATE SHIPPED TO SMELTERS					
Copper (Michigan)		40,272	24,979		
Lead (Wisconsin)		1,900		1,391	
Zinc (Wisconsin)		27,977			15,754

[1] All material treated at mills in 1951; none shipped directly to smelters. Some mass copper is hand-sorted rom crude copper ore in Michigan and some galena (lead sulfide) from lead ore in Wisconsin. The material s usually sorted at the mill and is included herein as part of the concentrates produced.

REVIEW BY STATES

MICHIGAN

Production of copper from Michigan mines in 1951 totaled 24,979 tons, 2½ percent less than in 1950. Virtually all this copper was produced by three companies: Calumet & Hecla Consolidated Copper Co. operating several underground mines and two tailings reclamation plants; Copper Range Co. operating the Champion mine; and Quincy Mining Co. operating one tailings reclamation plant. All operated at a relatively steady rate throughout the year. Of significance to the future of copper mining in Michigan's Upper Peninsula was the approval on November 15 of a $57,185,000 loan by the Reconstruction Finance Corporation to the White Pine Copper Co. for development of the White Pine copper deposit.

Extracts from the producing companies' annual reports follow:

From report of Calumet & Hecla Consolidated Copper Co.:

Exploration contracts have been made with the Government whereby the Company and the Government will share equally in the cost of exploring for copper ore in Northern Michigan and for zinc-lead ore in the Wisconsin-Illinois district. * * * In Northern Michigan we have received some encouragement, but a great deal of additional work must be done to determine whether we have located new ore bodies of commercial grade as a direct result of the exploration contract.

Because the present ceiling price of copper is unrealistic and too low in relation to increased costs of labor and supplies resulting from general inflation, the Company was forced to take advantage of Government subsidy in respect to four of our highest cost mines in Northern Michigan. The output from these mines represents about one-third of our current underground copper production. Under

Digitized by Google

contracts with the Defense Materials Procurement Agency, effective December 1, 1951, these mines should continue to operate at least for terms ranging from 12 to 17 months.

Applications are on file with the Defense Materials Procurement Agency seeking Government financing of the unwatering and rehabilitation of two of the Company's copper mines that were shut down in the 1930's. There is no assurance that the Government will approve these applications but, in the event of approval, the projects will make available 40 to 50 million pounds of copper per year over a period of at least 15 years.

* * *

Our seven copper mines and two reclamation plants operated at capacity throughout 1951 although the average yield per ton of rock was low. Labor and supply costs increased appreciably during the year but the price of refined copper was frozen for the entire year by the Office of Price Stabilization. As a result, our mining operations showed only a modest profit for the year.

* * *

EXPLORATIONS

* * * Contracts were made under which the Government has agreed to pay half the cost of certain explorations, to be repaid on a royalty basis if production results. These agreements provide for a total expenditure of $568,193 on explorations in Michigan and $158,519 on explorations in Wisconsin during a two-year period.

In Michigan, the Government is particpating in the cost of underground drifting and surface trenching. A drift, south of present workings on the Kearsarge Lode, has disclosed encouraging mineralization which justifies further work.

Without Government participation, the Company is exploring a part of the Knowlton Lode in Ontonagon County where spotty mineralization was discovered in 1939. Information will be sought on the pattern, grade and physical characteristics of the ore in order to determine whether the deposit can be exploited profitably.

From report of Copper Range Co.:

Mining was carried on throughout the year in the East Vein of the Champion Mine. The program of increasing tonnage was continued throughout the year although progress was not as rapid as desired. A total of 206,831 tons of ore were shipped to the mill. * * * Development and preparation work during the year was in excess of that required to replace the tonnage milled. Broken ore reserves were increased during the year from 101,000 tons to 133,000 tons at the end of the year.

* * *

On September 16th a wage increase was made subject to the approval of the Wage Stabilization Board. Concurrent increases in the cost of materials and supplies made it impossible to continue production on an economical basis at the ceiling price of 24.5 cents per pound. Consequently, the Company immediately began negotiations with the Defense Materials Procurement Agency for a subsidy to cover the current costs of production. By the end of the year an understanding had been reached with the Government whereby it agreed to pay to this Company subsidy payments with respect to copper produced from the East Vein (estimated during the two-year term of this contract at 6,372,000 pounds) equal to the difference between the ceiling price and 33.8 cents per pound. The understanding was formalized in an agreement with the Defense Materials Procurement Agency dated March 19, 1952 and is retroactive to January 1, 1952. The agreement terminates on December 31, 1953. Furthermore, it may be canceled on sixty days' notice by either the Government or the Company and will end automatically when copper price controls are removed.

The Mill at Freda operated throughout the year. In July regrind and concentrate cleaning circuits were put into operation which have raised the average grade of concentrate from 48 per cent to 60 per cent without increasing the overall milling costs and without additional capital expenditures. * * *

Digitized by Google

WHITE PINE COPPER COMPANY

The White Pine Copper Company, incorporated under the laws of the State of Delaware on November 21, 1950 and having an authorized capital of 300,000 shares of $10 par value, acquired 9,840 acres of the fee, mineral and surface rights initially required for the development of the project, including the ore body and all appurtenances, in consideration of the issue to Copper Range Company of 136,000 shares of its capital stock having an aggregate par value of $1,360,000. * * *

A loan in the amount of $57,185,000 was authorized by the Reconstruction Finance Corporation, acting under the Defense Production Act on November 15, 1951. Two amendments were made subsequently to reflect important changes in the terms and conditions of the original authorization. * * *

* * *

White Pine Copper Company has the right to require the Government to purchase up to 243,750 short tons (487,500,000 pounds) of the first 275,000 short tons of copper produced by the White Pine Copper Company at the floor price of 25.5 cents per pound, adjusted in accordance with changes in certain Government labor and commodity indices, reflecting changes in labor, material and other costs, as published by the United States Department of Labor, Bureau of Labor Statistics. The Government retains an option to buy all of the copper produced during the term of the contract at the higher of the then market price and the 25.5 cents floor price as adjusted by index changes. The contract terminates on December 31, 1961, subject to earlier termination upon certain contingencies.

* * *

During the year 2,788 tons of ore were mined at White Pine and sent to the pilot mill for testing purposes. * * *

From report of Quincy Mining Co.:

During 1951 operation of our Reclamation Plant has continued on a very satisfactory basis; the tons of stamp sands handled were somewhat less than during the previous year. The recovery of copper per tons of sands treated averaged 5.57 pounds, while this is very good it is about 5% less than for 1950. The waste tailings, discarded after treatment carried an average copper content of but 1.67 pounds per ton.

* * *

Our Reclamation Plant started the retreatment of stamp sands deposited in Torch Lake from our No. 1 Stamp Mill on November 1, 1943, and the dredge for pumping the sands from the Lake has been in continuous operation since that time; only a small tonnage remains to be treated from the number one mill sands, but there is probably enough to last until October 1952. At that time our dredging equipment will be moved to what is known as our No. 2 Stamp Mill sands. These are the waste tailings that were deposited in Torch Lake from our No. 2 Stamp Mill during the years between 1901 and 1920 at which time our No. 2 Stamp Mill was closed down. * * *

TABLE 4.—Mine production of copper in Michigan, 1947–51, in terms of recoverable metal

Year	Mines producing		Material treated		Copper	
	Lode	Tailings	Ore (short tons)	Tailings (short tons)	Short tons	Value
1947	11	4	1,962,258	3,167,516	24,184	$10,157,280
1948	11	3	2,165,112	2,325,124	27,777	12,055,218

1951	8	3	2,214,369	2,256,965	24,979	12,089,836

WISCONSIN

During 1951 Wisconsin mines produced and treated 499,971 tons of ore and an estimated 14,750 tons of tailings or boulder piles.

Digitized by Google

Twenty-five producers were active in 1951 compared with 11 in 1950, and production of lead and zinc was more than 2½ times that of 1950. Higher prices for both lead and zinc and Government assistance through exploration and development loans provided the chief incentives. Output in 1951 was 1,391 tons of lead and 15,754 tons of zinc. Tables 2, 3, and 5 give more detailed production data for the State.

The chief producers were: Calumet & Hecla Consolidated Copper Co. (an extract of the company annual report follows); Vinegar Hill Zinc Co.; Dodgeville Mining Co.; Mifflin Mining Co.; Benton Milling Co.; George M. Baker; and E. P. Scallon. Mifflin Mining Co. and E. P. Scallon were new operators in the State. Other producers include: Walter Kuhn; Pecatonica Mining Co.; Clarence F. Houtaker; Meekers Grove Mining Co.; Orthel Redfearn; Murray & Richards Co.; Whitechurch & Farr; Fred Hofer & Sons; Mayer & Thiede Mining Co.; and Mickey Mining Co.

The following is extracted from the annual report of the Calumet & Hecla Consolidated Copper Co.:

Exploration contracts have been made with the Government whereby the Company and the Government will share equally in the cost of exploring for copper ore in Northern Michigan and for zinc-lead ore in the Wisconsin-Illinois district. If commercial ore is discovered and mined, repayment of the Government's share will be made on a royalty basis. We have been fortunate in discovering a substantial tonnage of new ore in Wisconsin. * * *

* * *

The Company's zinc mine at Shullsburg, Wisconsin, was placed on a production basis at the beginning of the year. With the installation of additional underground loading and trucking equipment, production gradually increased as the year progressed, and at the year-end had reached the capacity of the mill. During the year 14,155 tons of zinc and lead concentrates were shipped. The underground and surface equipment is in good condition, and no additional major capital expenditures are contemplated for the present plant in 1952.

EXPLORATIONS

Explorations for copper and zinc ores were continued on the expanded scale started in 1950. Contracts were made under which the Government has agreed to pay half the cost of certain explorations, to be repaid on a royalty basis if production results. These agreements provide for a total expenditure of $568,193 on explorations in Michigan and $158,519 on explorations in Wisconsin during a two-year period.

* * *

Explorations in the Wisconsin-Illinois zinc district have disclosed more new ore than was mined during the year.

TABLE 5.—Mine production of lead and zinc in Wisconsin, 1947–51, in terms of recoverable metal

Year	Mines producing		Material treated		Lead		Zinc		Total value
	Lode	Tailings	Ore (short tons)	Tailings[1] (short tons)	Short tons	Value	Short tons	Value	
1947	48	4	257,456	240,554	1,166	$335,808	12,224	$2,958,208	$3,294,016

Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By F. F. Netzeband

GENERAL SUMMARY

DEFENSE programs of all the world powers during 1951 created a singular demand for metals on the entire domestic mining industry. Resultant high metal prices allowed mine operators in the West Central States—Missouri, Oklahoma, Kansas, and Arkansas—to mine the extensive marginal ores of these areas at maximum rate. Total mine production from these four States amounted to 11,783,062 tons of crude ore in 1951, which was 9 percent more than that produced in 1950. The grade of crude ore declined, resulting in similar declines in output of silver, copper, and lead. Zinc output, on the other hand, increased 14 percent.

The Government maintained its controls on prices and the allocation of metals to consumers throughout 1951. The ceiling price of lead was 17 cents and that of zinc 17.5 cents from January 1 to October 1. Each metal advanced 2 cents to 19 and 19.5 cents, respectively, for the last 3 months of 1951. Lead-concentrate price in the Tri-State district was $218.42 per ton until October 2, when it advanced to $246.50, and on November 1 decreased to $245.95, reflecting an increase in smelting charge. Zinc concentrates were quoted at $115.00 a ton until October 2, when they advanced to $135.00 a ton, as the domestic ceiling price of zinc was advanced 2 cents.

The total value of the silver, copper, lead, and zinc from the West Central States in 1951 amounted to $87,154,403, or $17,871,824 (26 percent) more than in 1950. Silver production was valued at $166,913, 22 percent less than in 1950; copper, $1,172,248, 6 percent less than in 1950; lead, $51,642,922, 16 percent more than in 1950; and zinc $34,172,320, 47 percent more than in 1950.

Mining activities in Texas in 1951 were primarily exploration projects in the Shafter, Van Horn, and Sierra Blanca areas in the southwestern part of the State. The total value of the mine production of gold, silver, copper, lead, and zinc in 1951 was $26,467—$1,120 for gold, $1,250 for silver, $483 for copper, $14,878 for lead, and $8,736 for zinc.

[1] These are the gold-, silver-, copper-, lead-, and zinc-producing States within Bureau of Mines Region VI.

Digitized by Google

Additional zinc values, not included in the above figures for Texas, were obtained from the slag-fuming plant of the American Smelting & Refining Co. at El Paso, which processed old zinc-lead-bearing slags with current hot slag. In production statistics, the metals (principally zinc) recovered from the current hot slags are credited to the various shippers of concentrates on the basis of assay content and are apportioned to the States from which the ore shipments originated. Specific data on the quantity of metals recovered from the old slag are not available.

The values of the metals reported in this chapter have been calculated at the average yearly metal prices given in table 1. Tonnage figures are short tons and "dry weight"; that is, they do not include moisture. Statistics on Texas are shown separately from those of the West Central States to maintain continuity with past years.

TABLE 1.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

[1] Price under authority of Gold Reserve Act of Jan. 31, 1934.
[2] Treasury buying price for newly mined silver July 1, 1946, to date—$0.9050505 ($0.905 used in 1947 for calculating purposes).
[3] Yearly average weighted price of all grades of primary metal sold by producers. Price in 1947 includes bonus payments by Office of Metals Reserve for overquota production.

TABLE 2.—Mine production of silver, copper lead, and zinc in Arkansas, Kansas, Missouri, and Oklahoma in 1951, by months, in terms of recoverable metal [1]

Month	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)
January	16,987	233	13,511	7,364
February	15,373	221	12,171	6,785
March	16,821	302	13,636	8,048
April	13,805	166	11,308	7,986
May	15,125	73	12,100	8,487
June	14,430	203	11,837	7,844
July	13,595	201	10,969	7,202
August	15,751	224	12,841	8,008
September	13,296	185	10,989	7,754
October	17,461	229	13,700	8,711
November	16,651	208	12,820	7,836
December	15,129	177	13,375	7,855
Total	184,424	2,422	149,257	93,880

[1] *See* footnote 2, table 3 for definition of mine production. References in that definition to gravel, gold, bullion, cyanidation, and amalgamation, however, are not applicable to the 4 States here covered, since gold has never been reported from these States and gold-extraction processes have not been used on their ores.

1950 [2]	935	49	1,715	2,454	2,221
1951 [2]	750	32	1,120	1,381	1,250
1885–1951	(4)	8,513	231,900	33,298,501	23,442,336

Year	Copper		Lead		Zinc		Total value
	Short tons	Value	Short tons	Value	Short tons	Value	
1947	6	$2,520	78	$22,464	22	$5,324	$50,478
1948 [3]	23	9,982	170	60,860	----------	----------	75,611
1949 [3]	24	9,456	132	41,712	----------	----------	55,003
1950 [2 3]	2	832	129	34,830	----------	----------	39,598
1951 [3]	1	483	43	14,878	24	8,736	26,467
1885–1951	1,365	393,316	5,387	674,439	834	131,287	24,873,278

[1] Includes recoverable metal content of ore shipped during the calendar year indicated.
[2] All of 1950 production was from 1 mine in Presidio County, which produced lead ore.
[3] Does not include zinc and lead recovered by the slag-fuming plant at the El Paso smelter from old accumulated slag resulting from operations in previous years.
[4] Data not available.

Gold.—A small amount of gold—32 ounces valued at $1,120—was produced in Texas in 1951. In 1950 Texas produced 49 ounces valued at $1,715.

Silver.—The production of silver in the West Central States in 1951 was 184,424 fine ounces, which at the Treasury price of $0.9050505 per ounce was valued at $166,913 compared with 236,273 ounces valued at $213,839 in 1950. All the silver produced in these States in 1951 was recovered incidental to the smelting of lead and lead-copper concentrates. These concentrates usually contain 1 to 2 ounces of silver per ton; however, all of the pig lead was not desilverized.

Copper.—The copper produced in the West Central States in 1951 amounted to 2,422 short tons valued at $1,172,248. This was 19 percent less in quantity and 6 percent less in value than was produced in 1950. All this production came from the lead-copper ores of Southeastern Missouri.

Lead.—The mine production of lead in 1951 in the West Central States decreased 9 percent in quantity but increased 16 percent in value because a higher metal price prevailed during the year. Missouri, the principal lead-producing State in the Nation, accounted for 123,702 tons, 32 percent of the Nation's lead recovered from domestic ores and 83 percent of the four-State output. Oklahoma produced 16,575 tons (11 percent of the four-State output), Kansas 8,947 tons (6 percent), and Arkansas 33 tons. The important lead-producing area of Southeastern Missouri accounted for 122,318 tons (99 percent of the Missouri output and 82 percent of the four-State output), while Southwestern Missouri produced 1,384 tons or 1 percent of Missouri output. The decrease in lead production in both the Southeastern Missouri region and the Tri-State district was due

Digitized by Google

to the mining of lower grades of ore, as evidenced by a lead-concentrate recovery factor of 2.40 for Southeastern Missouri and a lead recovery factor of 0.61 for the Tri-State district in 1951, compared with 2.70 and 0.86, respectively, in 1950. A 7-week work stoppage occurred in 1951 at the Missouri and Kansas operations of the National Lead Co. during April and May. All other major mines of the four-State area operated continuously throughout the year.

Zinc.—The 93,880 tons of recoverable zinc produced in the West Central States in 1951 comprised 91,553 tons (98 percent) from the Tri-State district, 2,277 tons (2 percent) from Southeastern Missouri, and 50 tons from Arkansas. In 1950 the Tri-State output was 80,558 tons, Southeastern Missouri 1,546 tons, and Arkansas 8 tons. This increase in recoverable zinc in 1951 was attributable to the material increase in crude-ore production, notwithstanding a marked decline in zinc-concentrate recovery from Tri-State district crude ore from 3.10 percent in 1950 to 2.74 percent in 1951.

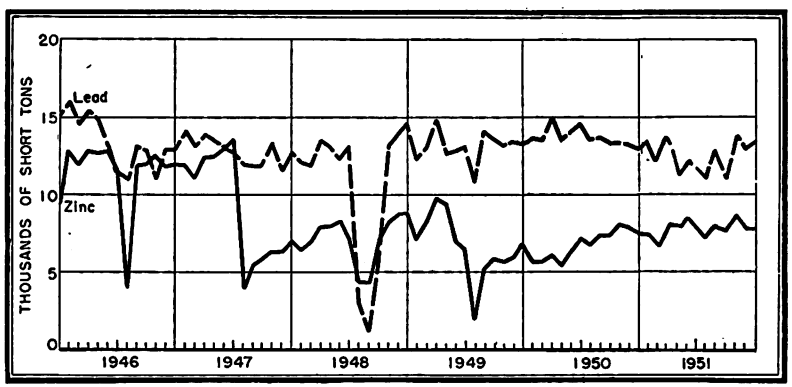

FIGURE 1.—Mine production of lead and zinc in Arkansas, Kansas, Missouri, and Oklahoma, 1946–51 by months, in terms of recoverable metal.

MINING AND METALLURGICAL INDUSTRY

Missouri, Oklahoma, Kansas, and Arkansas.—There were 289 mines, 25 mine mills, and 3 tailings mills operating in the West Central States in 1951 compared to 255 mines, 22 mine mills, and 4 tailings mills in 1950. Several mine mills of the St. Joseph Lead Co. in St. Francois County, Mo., operated on a mixed crude ore-tailings feed at intervals during the year. This company was also constructing 2 new mills, 1 at Hayden Creek and the other at Indian Creek. National Lead Co. was engaged in an extensive diamond- and churn-drilling campaign and in constructing an addition to its Madison mill to treat complex copper-cobalt-nickel-iron ores.

Extensive diamond and churn drilling was limited to the major mining companies in Southeastern Missouri, although in the Tri-State district 10 companies each reported churn drilling 1,000 feet or more. National Lead Co. drove a long development drift to open an ore body in an adjoining lease.

There were 4 horizontal retort zinc smelters, 1 zinc pigment plant, and 2 lead smelters active in the West Central States in 1951. There

Digitized by Google

were 29,700 retorts in the zinc smelters, having an annual rated capacity of more than 200,000 tons of metal. These smelters received concentrates from several western mining States, the Tri-State district, and foreign countries. Three of the smelters were in Oklahoma—Bartlesville, Blackwell, and Henryetta—and one at Fort Smith, Ark. The two lead smelters, 1 of which also had a refinery, were at Herculaneum, Mo., and Galena, Kans. Their combined annual capacity was 110,000 tons of pig lead. Smelter labor was adequate during 1951, few companies requiring over 2 percent of their labor force for full operation. A work stoppage closed the Herculaneum smelter of St. Joseph Lead Co. from October 18 to December 31, 1951.

Texas.—The total mine production of gold, silver, copper, lead, and zinc and their respective values for Texas from 1885 to 1951 are given in table 5. The early statistical records were compiled by the U. S. Geological Survey; the U. S. Bureau of Mines assumed responsibility for these records from 1924 to date.

The smelting industry of Texas in 1951 comprised 2 retort and 1 electrolytic zinc smelters, 1 copper smelter and 1 lead smelter. Ores and concentrates were received from various western mining States and foreign countries. In addition, these smelters treated substantial tonnages of smelter residues and matte.

The El Paso Smelting Works of the American Smelting & Refining Co. included a copper smelter and a lead smelter, each with an annual capacity of 300,000 tons of material, and a slag-fuming plant, which treated old cold slags and current hot slags, recovering zinc as an oxide fume and some lead. This company also operated a horizontal-retort zinc smelter at Amarillo and an electrolytic zinc smelter at Corpus Christi; these smelters had a combined annual capacity of about 100,000 tons of zinc.

The Phelps-Dodge Corp. operated its Nichols electrolytic copper refinery at El Paso, processing blister copper from its Arizona smelters into refined copper. This plant had an annual capacity of 240,000 tons of electrolytic copper.

The Machovec-retort zinc smelter of the American Zinc Co. of Illinois, which had an annual capacity of approximately 37,000 tons of zinc, processed ore and concentrates, as well as zinc fumes, from several western mining States and foreign countries. Smelter labor was adequate most of the year.

ORE CLASSIFICATION

Table 6 gives details on classes of ore, metal recovered by classes of ore, and the number of mines in each class for the West Central States in 1951. The basis of this classification is given in the Gold and Silver chapter of this volume. This classification allows comparison with ores produced in the western mining States as reported in State chapters. Additional data on tenor of ores, concentrates produced, metal content of both ore and concentrates, and average values are given in subsequent tables in the Tri-State District and Review by States section. Such tables are omitted for Arkansas and Texas because only small-scale intermittent production occurred for the past several years.

TABLE 6.—Mine production of silver, copper, lead, and zinc in Arkansas, Kansas, Missouri, and Oklahoma in 1951, by class of ore or other source material, in terms of recoverable metal

Source	Number of mines	Material sold or treated (short tons)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)
Lead ore [1]	14	7,367,283	184,424	2,422	122,467	2,278
Zinc ore [2]	93	1,731,283	----------	----------	1,414	26,033
Zinc-lead ore	182	5,005,548	----------	----------	25,376	65,569
Total: 1951	289	14,104,114	184,424	2,422	149,257	93,880
1950	255	12,759,923	236,273	2,982	164,846	82,112

[1] Includes lead-copper ore from one mine; also 1,574,379 tons of old tailings remilled, concentrates from which were mixed with those from crude ore.
[2] Includes 746,673 tons of old tailings yielding 3,212 tons of recoverable zinc and 24 tons of recoverable lead.

TRI-STATE DISTRICT

Because of the marginal nature of the remaining ore reserves, mine production in the Tri-State district (Southwestern Missouri, Oklahoma, and Kansas) is largely determined by prevailing metal prices. With the Nation's defense program consuming large quantities of metals, resultant high metal prices for zinc and lead stimulated maximum production.

The majority of the mines in the Tri-State district operated throughout 1951; a few mines were, however, compelled to shut down for lack of ore reserves. The supply of mine labor was reported to be satisfactory all year.

TABLE 7.—Mine production of lead and zinc concentrates in the Tri-State district (Kansas, Oklahoma, and Southwestern Missouri), 1947–51

Year	Material milled (short tons)	Concentrates produced (short tons)		Concentrate recovery (percent)		Average assay of concentrates (percent)		Average value per ton of concentrates	
		Lead	Zinc	Lead	Zinc	Lead	Zinc	Lead	Zinc
FROM CRUDE ORE									
1947	6,229,702	31,842	181,662	0.51	2.92	77.41	59.68	$190.72	$107.42

TABLE 8.—Quoted prices for 60-percent zinc concentrates and 80-percent lead concentrates at Joplin in 1951

[E&MJ Metal and Mineral Markets]

Zinc concentrates		Lead concentrates	
Period	Price per short ton	Period	Price per short ton
Jan. 1–Oct. 1	[1] $115.00	Jan. 1–Oct. 1	[1] $218.42
Oct. 2–Dec. 31	135.00	Oct. 2–Oct. 31	246.50
		Nov. 1–Dec. 31	[2] 245.95

[1] Metal prices under OPS price ceilings throughout 1951.
[2] Drop due to increased smelter charge.

The district produced 170,263 tons of zinc concentrates valued at $21,023,818, and 36,300 tons of lead concentrates valued at $7,720,550 from 5,990,100 tons of crude ore and 746,673 tons of tailings in 1951. These concentrates yielded 91,553 tons of recoverable zinc and 26,906 tons of recoverable lead. The grade of ore declined in 1951, reversing the upgrading trend of the past 4 years. The average zinc-concentrate price received was $123.48 per ton, or 33 percent higher than in 1950, while the average lead concentrate price received was $212.69, or 39 percent higher.

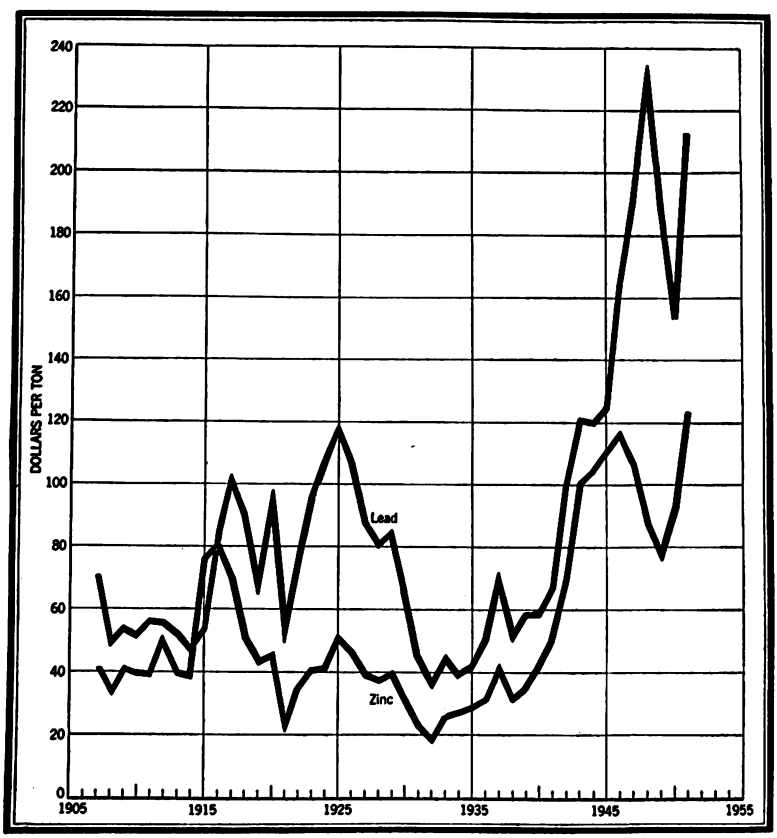

FIGURE 2.—Average prices received by sellers per ton of concentrate in the Tri-State district, 1907–51.

Digitized by Google

The five leading zinc-producing companies in the Tri-State district in 1951 were the Eagle-Picher Co. (Oklahoma and Kansas), American Zinc, Lead & Smelting Co. (Oklahoma), National Lead Co. (Kansas), Federal Mining & Smelting Co. (Oklahoma and Missouri), and Dale Mining Co. (Missouri).

The five principal lead-producing companies were the Eagle-Picher Co. (Oklahoma and Kansas), American Zinc, Lead & Smelting Co. (Oklahoma), National Lead Co. (Kansas), Federal Mining & Smelting Co. (Oklahoma and Missouri), and Bilharz Mining Co. (Kansas).

There were 280 mines, 19 mine mills, and 3 tailings mills operating in the district during 1951 compared to 248 mines, 16 mine mills, and 3 tailings mills in 1950. The depth of 328 producing shafts

ranged from 30 to 450 feet. The several open pits operating in Southwestern Missouri ranged in depth from 10 to 90 feet.

REVIEW BY STATES

MISSOURI

Missouri has been the chief lead-producing State in the Nation for 44 consecutive years and the St. Joseph Lead Co. of Bonne Terre, Mo., the largest individual lead-producing company. A summary of the State production of silver, copper, lead, zinc, and other minerals from the earliest records through 1947 was published in 1949.[2]

In 1951 Missouri produced 178,531 tons of lead concentrates, 99 percent in the Southeastern Missouri lead belt and 1 percent in Southwestern Missouri, and 21,845 tons of zinc concentrates, 80 percent originating in Southwestern Missouri and 20 percent in Southeastern Missouri. Silver and copper were also recovered as byproducts in the smelting of lead and of complex lead-copper-cobalt-nickel-iron concentrates produced in the Southeastern Missouri region. Silver recovery amounted to 184,424 fine ounces in 1951, a decline of 22 percent from 1950 recovery. Copper production in 1951 was 2,422 short tons, 19 percent less than that produced in 1950. No value was attributed to the silver in the sale of lead concentrates, as the amount recovered per ton of concentrates was so small.

Southeastern Missouri.—Work stoppages prevented the mining industry from continuous operation in 1951. Mine production increased 4 percent to 7,359,441 tons of crude ore, but lead production decreased 8 percent to 122,318 tons. The decline was due to a marked decrease in the grade of the ore mined in 1951 as compared with 1950 recovery. Zinc production, which is largely dependent on the re-treatment of old tailings, showed a 47-percent increase to 2,277 short tons.

St. Joseph Lead Co. operated its group of large mines and four mills, Bonne Terre, Desloge, Federal, and Leadwood in St. Francois County, the entire year. Development work in the St. Francois County mines consisted of 85,700 feet of tunneling, 1,375,000 feet of diamond drilling, and 32,000 feet of churn drilling. The company also operated the Mine LaMotte mine and 2,000-ton mill in Madison County. Development work at the mine amounted to 3,968 feet of tunnels, 34,000 feet of diamond drilling, and 6,100 feet of churn drilling.

The National Lead Co. operated its Madison lead-copper mine and 1,200-ton all-flotation mill at Fredericktown. Exploration and development work consisted of extensive diamond and churn drilling in the Fredericktown area.

The Catherine-Fleming mine at Fredericktown was operated by the Fredericktown Lead Co., whose holdings were acquired by the Blue Bonnett Mining Co. early in the year. This company later sold its holdings to the Midwest Mining & Milling Co. Exploration and development work of the 3 companies consisted of 32 feet of shaft work and 2,100 feet of churn and diamond drilling.

1951	176,764	32,484,309	4,475	509,658	122,318	42,322,028	[7] 2,277	828,828

[1] Based on Southeastern and Central Missouri ore ("dirt") and old tailings treated at mills during calendar year indicated.
[2] Includes zinc-lead carbonate concentrates.
[3] In calculating metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the values of concentrate ("ore") and metal it should be borne in mind that the value given for the concentrate is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.
[4] Values given are to a certain extent arbitrary, as part of the lead concentrates are smelted by the producer.
[5] Includes zinc recovered from lead-smelter slag.
[6] Includes zinc recovered from lead-smelter byproducts.
[7] Includes zinc recovered from byproduct matte from lead smelting as follows: 1950, 180 tons; 1951, 138 tons.

TABLE 10.—Tenor of lead ore and concentrates in Southeastern Missouri disseminated-lead district, 1947–51

	1947	1948	1949	1950	1951
Total lead ore [1] ..... short tons	5,856,334	5,384,861	7,066,443	7,091,257	7,359,441
Galena concentrate in ore ..... percent	3.12	2.70	2.54	2.70	2.40
Average lead content of galena concentrates ..... do	72.22	70.60	71.60	71.19	70.66
Average value per ton of galena concentrates	$173.49	$209.11	$181.75	$148.99	$183.77

[1] Includes lead-copper ore. Includes old tailings remilled: 1947—301,324 tons; 1948—1,164,356 tons; 1949—1,409,098 tons; 1950—1,025,502 tons; 1951—1,574,379 tons.

Southwestern Missouri.—Mining activities continued to increase in this region in 1951, particularly open-pit operations. Mine production increased 124 percent to 714,060 tons of ore, yielding 17,370 tons of zinc concentrates (42 percent increase) and 1,767 tons of lead concentrates (4 percent increase) when compared with 1950 production. Open-pit operations accounted for 43 percent of the crude-ore production, which yielded 18 percent of the zinc and 47 percent of the area's lead production. Federal Mining & Smelting Co. operated its Duenweg mines and mill and was the largest producer in the region. Potter-Sims Mines, Inc., operated the Snapp and Evans lease (old Sucker Flat) open pits most of the year, although adverse weather and stripping overburden curtailed production at intervals. B. F. & H. Mines, Inc., worked its Bull Frog open pit on the Swartz land near Joplin. Dale Mining Co. mines near Stark City were active all year.

OKLAHOMA

Oklahoma continued as the principal zinc- and lead-producing State in the Tri-State district for the thirty-eighth consecutive year. This record began in 1913, when the famous Picher field was brought into production. In 1951 the State produced 58 percent of the recoverable zinc and 62 percent of the recoverable lead output of the Tri-State district. The 4,208,736 tons of crude ore, old tailings, and slimes treated in Oklahoma in 1951 yielded 99,612 tons of zinc concentrates, 14 percent more than was produced in 1950, and 22,613 tons of lead concentrates, 17 percent less than that produced in 1950. The quantity of recoverable zinc was 53,450 tons and recoverable lead was

Digitized by Google

16,575 tons. The grade of both zinc and lead in the ore declined from that mined in 1950, while the grade of each in the tailings remilled in 1951 increased.

TABLE 13.—Mine production of lead and zinc in Oklahoma, 1947–51, and total, 1891–1951, in terms of concentrate and recoverable metal [1]

[1] Figures represent metal content of the crude ore ("dirt") only insofar as it is recovered in the concentrate; data on tailing losses not available.

The large custom Central mill of the Eagle-Picher Co. treated nearly 50 percent of the crude ore mined in the Tri-State district in 1951. About 70 percent of the Central mill's feed came from Oklahoma mines and 30 percent from Kansas mines. The Bird Dog mill continued to treat the slimes of the Central mill. The Eagle-Picher Co. operated 33 mines in Oklahoma during 1951. Other Oklahoma producers who shipped to the Central mill included Federal Mining & Smelting Co., Buffalo Mining Co., John Henderson, Frank Hudson, Tongaha Mining Co., Wesah Mining Co., and W. M. & W. Mining Co.

The American Zinc, Lead & Smelting Co. acquired the Nellie B. Mining Co. properties in October 1951, thus making it the second

Digitized by Google

largest producer in the district. The transaction involved the transfer of 1,360 acres of contiguous leases, including the Lawyers, Rialto, Evans-Wallower, and Admiralty, and 3 mine mills, with daily capacity exceeding 3,000 tons or ore.

Other Oklahoma producers in 1951 included the Harris, Helen H., Dines, C. & M., W. M. & W. and Beck mining companies.

The Sooner Milling Co. operated its Sooner tailings mill throughout the year. Britt and Britt operated their tailings mill until June 1951 when they dismantled the mill.

KANSAS

Kansas production in 1951 included 1,733,827 tons of crude ore and 80,150 tons of tailings, which yielded 53,281 tons of zinc concentrates (5 percent more than in 1950) and 11,920 tons of lead concentrates (2 percent less than in 1950). These mines produced 31 percent of the Tri-State district zinc concentrates and 33 percent of the district lead concentrates. Output of recoverable zinc in Kansas was 28,904 tons and of recoverable lead, 8,947 tons.

Approximately 55 percent of the crude ore mined in Kansas was concentrated at the Central mill of the Eagle-Picher Co. at Cardin, Okla. Kansas shippers to the Eagle-Picher Central mill in Oklahoma included Bilharz, C. K. & E., Bob White, Mark Twain, S. S. & C., Linda Lou and Midcontinent mining companies. Other Kansas producers were Bailey, Mid Century, Roanoke, Little Ben, Tiger, MacArthur, and Contack mining companies. Companies operating mills in Kansas were the W. M. & M. (Brewster), Dines Mining Co. (Blue Mound), and Wade-Rea Mining Co. (Wade-Rea).

TABLE 15.—Mine production of lead and zinc in Kansas, 1947–51, and total, 1876–1951, in terms of concentrate and recoverable metal [1]

Year	Mines producing	Lead concentrates (galena)		Zinc concentrates (sphalerite)		Recoverable metal content [2]

1876–1951		796,021	65,073,020	5,219,281	241,711,613	607,444	78,482,161	2,710,051	378,457,088

[1] Based on Kansas ore ("dirt") and old tailings treated at mills during the calendar year indicated.
[2] In calculating metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the values of concentrate ("ore") and metal it should be borne in mind that the value given for the concentrate is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.

The National Lead Co. operated its several mines and No. 8 Ballard mill during most of 1951; a brief work stoppage curtailed production temporarily. Its production was the second largest in the State in 1951.

Small lots of ore were reported from the Galena, Crest-line, and Waco areas during the year.

ARKANSAS

Production of zinc concentrates in Arkansas in 1951 amounted to 124 tons (mostly carbonates) compared with 17 tons in 1950. Lead-concentrates production amounted to 45 tons compared with 11 tons in 1950. Most of the production of zinc and lead came from the St. Joe district in Searcy County and the Rush district in Marion County. Small lots were also reported from Ponca in Newton County and near Harrison in Boone County.

The price increases of both zinc and lead stimulated prospecting activity, but failed to increase production materially.

TEXAS

Presidio County.—R. I. Carr, who has operated in Presidio County for the past several years, did considerable exploratory work on a large block of leases in the Shafter area in 1951. A prospect shaft and trenching showed evidence of lead mineralization over a considerable area. The old Presidio mine of the famous Shafter area produced over 30,000,000 ounces of silver from 1887 to 1942.

Culberson County.—Several small shipments of ore came from the exploratory projects of the Carpenter Exploration Co. during the latter part of 1951. Surface trenching and several prospect shafts on leases in the Van Horn and Sierra Diablo Mountains of Culberson and Hudspeth Counties, 30 miles south and west of Van Horn, Tex., exposed favorable evidence of copper and lead-zinc mineralization. Work was continuing at the year end to further develop these "shows" of ore.

Hudspeth County.—The D'Argon Mining Co. of Sierra Blanca had developed promising showings of lead and zinc ore in the old Bonanza mine, in the Quitman Mountains of Hudspeth County. A development raise and several hundred feet of drift yielded enough ore to warrant shipments to a concentrating mill. The company continued its development projects at the year end.

Montana

Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By Richard H. Mote

GENERAL SUMMARY

GOLD production in Montana in 1951 dropped to a near record low as output fell 41 percent from 1950. Not since 1862 has the quantity of the precious metal recovered from the State's ores and placers been so small. Contrasting the decline in gold-mining activity were increases of varying magnitudes in the production of the other major nonferrous metals. Zinc output reached the highest annual level since 1920, and lead production was the greatest of any year since 1940. Although the output of copper was the largest since 1948, production in 1951 was substantially below the high outputs of 1900–20, which did much to establish Montana as a leading copper-producing State.

The total value of the five metals increased from $54,956,689 in 1950 to $73,149,813 in 1951, a gain of 33 percent. Gold accounted

Gold.—Montana's gold output in 1951 dropped to the lowest level since 1862 when production totaled 29,025 ounces. Output declined sharply from both lode and placer operations. Of the State gold in 1951, 42 percent was derived from gold and silver ores (47 percent in 1950), 54 percent from base metal ores (47 percent in 1950), and nearly 4 percent from placers (6 percent in 1950). Ores milled yielded 74 percent of the total gold and ores shipped to smelters, over 22 percent.

Gold producers in Montana in 1951 with an output of 1,000 ounces or more were the properties of the Anaconda Copper Mining Co. (copper ore and waste materials and zinc-lead ore and dumps) at Butte, the Estelle mine of the McLaren Gold Mines Co. in Park County (gold ore), the Drumlummon mine of the St. Louis Drumlummon Mines in Lewis and Clark County (gold ore), the Cornucopia mine operated by Henry A. Schute (gold ore), and the American Pit (Victoria) mine of the Victoria Mines, Inc. (gold ore), both in Madison County. From these five properties came 78 percent of the State total gold in 1951.

Silver.—Production of silver decreased slightly in 1951. Yield of the metal from zinc-lead ores increased as compared with 1950, but the gain was more than offset by a substantial decline in recovery from copper ore. In 1951 operations of the Anaconda Copper Mining Co. at Butte supplied 93 percent of the State total silver output. Other important silver producers, in order of decreasing output, were the Mike Horse mine of the Mike Horse Mining & Milling Co. at Flesher in Lewis and Clark County, the Alta property of the Lahey Leasing Co. in Jefferson County, and the Contact Mining Co. Scratch Awl mine in Granite County. These four operations furnished 96 percent of the State's silver production in 1951.

Zinc-lead ore supplied 71 percent of the State silver in 1951, copper ore, 24 percent; gold and silver ores and old tailings, 3 percent; and lead, lead-copper and zinc ores and old slag together, 2 percent. Ore milled yielded 95 percent of the total silver, and smelting ores almost 5 percent. A small quantity of silver was recovered from placer operations.

Copper.—Output of copper in Montana in 1951 increased 5 percent over the 1950 production. Although operations at the Butte properties of the Anaconda Copper Mining Co. were handicapped by a shortage of skilled miners, the company supplied nearly 98 percent of the State copper mined in 1951. Other producers of copper in Montana, in order of decreasing output, were the Sarsfield mine worked by Ted Farrow and the Bullwhacker property operated by Norman Rogers, both in Silver Bow County, the Estelle mine in Park County, and the American Pit (Victoria) mine in Madison County.

Digitized by Google

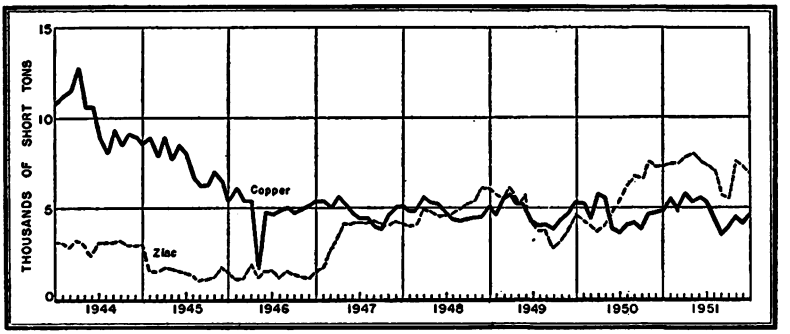

FIGURE 2.—Mine production of copper and zinc in Montana, 1944–51, by months, in terms of recoverable metal.

Lead.—Lead production in 1951 advanced 9 percent over 1950 and was the greatest in any year since 1940. Most of this gain was due to an increase in the tonnage of zinc-lead ore produced from mines operated by the Anaconda Copper Mining Co. and to a substantial rise in production from the Mike Horse mine, which was operated all of 1951 in contrast to 6-month operation in 1950. Anaconda company owned and leased operations in 1951 supplied 78 percent of the State lead; other operations that produced over a million pounds of recoverable lead each were the Mike Horse property and the American Smelting & Refining Co. Jack Waite mine, in Sanders County, and the Blacktail property of the Linton Mines in Missoula County. These four companies supplied 91 percent of the total lead produced in the State in 1951. Of the total lead 89 percent was recovered from zinc-lead ore, 7 percent from lead ore, 3 percent from gold and silver ores, and 1 percent from zinc ore and old slag.

Zinc.—Yield of zinc from Montana ores in 1951 advanced 26 percent over the 1950 figure and reached the highest annual level since 1920, largely the result of a substantial increase in production at the Butte Hill mines and dumps of the Anaconda Copper Mining Co. Also significant was the fact that 1951 marked the fourth year in the State's mining history in which zinc production exceeded the output of copper. During the year, Anaconda company owned and leased operations at Butte supplied 94 percent of the State's zinc output. Other important zinc producers, in order of decreasing output, were the East Helena old slag dump, the Mike Horse property, the Jack Waite mine, the Scratch Awl property, and the Taylor-Knapp Co. True Fissure mine in Granite County. These six operations produced over 99 percent of the State total zinc output. Zinc-lead ore supplied 96 percent of the State zinc in 1951, zinc ore and old slag nearly 4 percent.

MINING INDUSTRY

Although the number of producing mines in Montana in 1951 as compared with 1950, declined from 284 to 214, ore production increased 10 percent to 3,965,875 short tons, gains of varying magnitude in copper, lead, and zinc content were recorded also. Production was curtailed somewhat by labor shortages reported in several operating areas and the nationwide mine, mill, and smelter labor strike from August 27 to September 7; nevertheless, ore production at many properties advanced substantially over the 1951 level. Much of the increased activity in mining and development at established properties was stimulated by the sustained high level in market prices of copper, lead, and zinc and a strong demand for metals to support the Nation's defense program. At the Butte properties of the Anaconda Copper Mining Co. construction on the Greater Butte project proceeded on schedule. Work on surface facilities was substantially completed

Digitized by Google

during the year. The schedule of underground mine preparation for the project was maintained and initial mining operations by block-caving methods were expected to begin in early 1952.

The production of zinc-lead and zinc ores (including old slag) increased 19 and 16 percent, respectively, in the State in 1951, but copper ore mined declined 2 percent, and there was a drop of 37 percent in production of gold and silver ores and old tailings. Of the 3,965,875 tons of ore treated during the year, 68 percent was zinc-lead, lead, zinc, and lead-copper ores, 29 percent was copper ore, and 3 percent was gold and silver ores and old tailings and old lead blast furnace slag.

Field teams of the Defense Minerals Administration (Defense Minerals Exploration Administration after August 28, 1951, as a result of a presidential executive order) made up of Bureau of Mines engineers and geologists of the Federal Geological Survey, examined a number of Montana mining properties for eligibility under the Federal Government program of assisting in the exploration of unknown or undeveloped sources of strategic and critical minerals and metals. As a result of this activity, 14 exploration contracts totaling $460,424 were approved for properties producing copper, lead, or zinc. Data on mines and mineral deposits in several Montana counties were published.[1]

TABLE 6.—Mine production of gold, silver, copper, lead, and zinc in Montana in 1951, by class of ore or other source material, in terms of recoverable metal

Source	Number of mines[1]	Material sold or treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)

METALLURGICAL INDUSTRY

Of the 3,965,875 tons of material sold or treated in Montana in 1951, 3,856,554 tons (97 percent) went to mills and 109,321 tons (3 percent) to smelters, compared with 97 and 3 percent, respectively, in 1950. The 3,856,554 tons treated at mills were distributed as follows: 11 plants, 2,664,095 tons of zinc-lead ore; 3 plants, 1,124,434 tons of copper ore; 16 plants, 50,000 tons of gold and silver ore; 4 plants, 16,366 tons of lead ore; and 3 plants, 2,559 tons of zinc ore.

The Anaconda Copper Mining Co. copper concentrator, zinc concentrator, and copper smelter (all at Anaconda) and the two electrolytic zinc plants (at Anaconda and Great Falls) operated throughout the year. The zinc plants treated 446,276 tons of zinc concentrates from many sources containing 474,873,818 pounds of zinc, compared with 466,695 tons containing 494,909,180 pounds of zinc in 1950. The company slag-fuming plant at East Helena was operated throughout the year and treated 208,628 tons of hot slag and old lead-blast-furnace slag compared with the 222,892 tons in 1950; output of zinc-lead fume decreased from 37,754 tons in 1950 to 36,113 in 1951. The addition to zinc-plant facilities of a sixth unit at Anaconda was expected to be completed during 1952.

The lead smelter of the American Smelting & Refining Co. at East Helena operated throughout 1951 and treated chiefly lead-silver concentrates from mines in Idaho, crude ore, concentrates, and old tailings from numerous districts in Montana and residues from the electrolytic zinc plants at Anaconda and Great Falls.

Definitions used in ore classification are given in the Gold and Silver chapter of this volume.

TABLE 7.—Mine production of gold, silver, copper, lead, and zinc in Montana in 1951, by method of recovery and type of material processed, in terms of recoverable metal

Method of recovery and type of material processed	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Lode:					
Amalgamation [1]	825	42			
Concentration, and smelting of concentrates [1]	21,747	6,089,719	103,204,588	39,067,111	165,116,761
Direct smelting:

[1] Includes some old tailings.
[2] From copper, lead and zinc-lead ore.
[3] Includes 20 tons mill cleanup and 169 tons of old tailings.
[4] Includes 1,881 tons of old tailings.
[5] Includes 2 tons smelter cleanup
Includes 20,688 tons old slag.

REVIEW BY COUNTIES

BEAVERHEAD

Lead ore constituted nearly 70 percent of the total output of Beaverhead County in 1951; except for 18 tons shipped from the H & S mine in the Chinatown district, all of it came from mines in the Argenta district. Ida B. Hand, operating the Maulden mine throughout the year, recorded the largest production. A total of 2,294 tons

of lead ore, containing 71 ounces of gold, 9,248 ounces of silver, 28,313 pounds of copper, 625,387 pounds of lead, and 145,806 pounds of zinc were shipped to a smelter. W. I. Gardner and the Jack Group Mining Corp. worked the Jack mine in Clark Canyon, 18 miles northwest of Dillon, during most of the year and shipped 390 tons of lead smelting ore containing 135 ounces of gold, 7,206 ounces of silver, 784 pounds of copper, 62,320 pounds of lead, and 4,100 pounds of zinc.

BROADWATER

Important producers in the county included the North Star group in the Cedar Plains district, operated by Roy E. Nichols, and the Marietta claim in the Park or Indian Creek district, worked by Marietta Mines. Operations at the North Star group recovered 253 tons of zinc carbonate ore containing 2 ounces of gold, 784 ounces of silver, 1,993 pounds of copper, 16,937 pounds of lead, and 148,486 pounds of zinc, which were shipped to a smelter in Utah.

Cedar Plains District.—Zinc ore was the principal output of the Cedar Plains district in 1951. In addition to production from the North Star group, a total of 208 tons of ore containing 1 ounce of gold, 938 ounces of silver, 264 pounds of copper, 11,912 pounds of lead, and 90,795 pounds of zinc was shipped from the Ruby Silver property. Wayne Miller and James Holling worked the Keating mine during a portion of the year and shipped 132 tons of zinc ore containing 100 ounces of gold, 74 ounces of silver, 375 pounds of copper, 2,583 pounds of lead, and 28,974 pounds of zinc.

Park or Indian Creek District.—Except for a small quantity of gold recovered from placer gravel, all the district output came from gold ore, the principal producer of which was the Marietta mine.

CASCADE

Output for the year, all from the Montana district, comprised 182 tons of zinc-lead ore from the Broadwater-Moulton property, 720 tons of zinc-lead ore from the Galt mine, 11 tons of lead ore from the Hartley claim, and 7 tons of lead-copper ore from the Silver Dyke Group.

DEER LODGE

Gold ore continued to be the source of metal production in Deer Lodge County in 1951. Principal producer was the Acme Co., which operated the Gold Coin mine continuously throughout 1951. A total of 1,050 tons of gold ore, treated by amalgamation, yielded 574 ounces of gold and 14 ounces of silver.

GRANITE

Glen Hawe operated the Sunrise mine in the First Chance district from January 1 to May 5 and shipped 558 tons of copper smelting ore containing 108 ounces of gold, 590 ounces of silver, and 28,935 pounds of copper.

The Master Mining Co. did placer mining on upper Gold Creek in the Gold Creek and South Gold Creek district and washed about 25,000 cubic yards of gravel, which yielded 130 fine ounces of gold and 21 fine ounces of silver.

Digitized by Google

Flint Creek District.—The largest operation in the district and the county was the True Fissure mine and 80-ton mill, worked throughout 1951 by the Taylor-Knapp Co. A substantial tonnage of manganese ore, containing varied quantities of gold, silver, copper, lead, and zinc, was milled during the year in the company gravity- and magnetic-separation plant. Peter Antonioli, lessee, worked the Scratch Awl mine throughout 1951 and shipped 2,275 tons of zinc-lead ore containing 41 ounces of gold, 63,909 ounces of silver, 9,570 pounds of copper, 237,360 pounds of lead, and 610,681 pounds of zinc to a custom mill in Utah.

JEFFERSON

Colorado District.—The bulk of the mining activity within the county in 1951 was centered in the Colorado district where most of the output comprised 13,769 tons of dry silver ore from the Alta mine, 2,208 tons of gold-silver ore from the Gregory Mines dump, 299 tons of gold-silver tailings from the Flagstaff property, and 237 tons of silver ore from the Mount Washington dump.

Elkhorn District.—Louis Peura worked the Elkhorn dump during the year and shipped 2,366 tons of old silver tailings containing 48 ounces of gold, 16,063 ounces of silver, 2,873 pounds of copper, 51,912 pounds of lead, and 169,671 pounds of zinc to a smelter. The Elkhorn mine, operated 6 months during 1951 by the Elkhorn Mining Co., yielded 912 tons of silver smelting ore containing 10 ounces of gold, 8,913 ounces of silver, 832 pounds of copper, 20,948 pounds of lead, and 68,585 pounds of zinc. The New Elkhorn Queen Mining Co. shipped 2,089 tons of lead smelting ore and 221 tons of gold-silver dump ore from the Elkhorn Queen mine.

Most of the output in the Whitehall district in 1951 came from 555 tons of lead smelting ore shipped from the Carbonate mine, 189 tons of gold smelting ore from the Lucky Hit mine, and 110 tons of lead smelting ore from the Whitehall mine.

JUDITH BASIN

All metal production in the county in 1951 came from mines in the Barker district. Thorson and Brazee worked the Edwards lode all year and shipped 125 tons of zinc-lead smelting ore containing 4 ounces of gold, 2,899 ounces of silver, 507 pounds of copper, 75,929 pounds of lead, and 29,577 pounds of zinc.

LEWIS AND CLARK

Heddleston District.—The Mike Horse Mining & Milling Co. operated its Mike Horse mine throughout the year and treated 40,975 tons of zinc-lead ore in the company 300-ton flotation mill. A total of 2,235 tons of lead concentrate and 2,800 tons of zinc concentrate were recovered in the milling operation. Development at the property during the year included 209 feet of crosscuts and 116 feet of diamond drilling.

The second largest operation within the county in terms of ore tonnage was the Drumlummon mine in the Marysville district, worked by the St. Louis Drumlummon mines. Gold ore totaling

Digitized by Google

3,426 tons and containing 1,398 ounces of gold, 11,472 ounces of silver, 4,115 pounds of copper and 25,389 pounds of zinc, was shipped to a smelter.

The metals credited to the Smelter district came from 20,439 tons of old zinc slag, treated at the East Helena slag-fuming plant of the Anaconda Copper Mining Co. The tonnage treated in 1951 compares with 20,764 tons similarly treated in 1950.

Missoula Lincoln Metals Co. operated a dragline dredge and nonfloating washing plant on the Abraham, Bluebird, Dollar, and Half Dollar placers in the Lincoln district and washed about 666,000 cubic yards of gravel.

MADISON

The Victoria Mines, Inc., American Pit (Victoria) mine in the Silver Star district continued in 1951 to be the largest producer in Madison County. During the year a total of 18,450 tons of gold ore containing 1,552 ounces of gold, 6,785 ounces of silver, and 278,218 pounds of copper were shipped to a custom mill for treatment.

In terms of ore output, the Virginia City district ranked second among the producing mining districts in the county in 1951. Henry A. Shute worked the Cornucopia property during most of the year and shipped 4,286 tons of gold-silver smelting ore containing 1,420 ounces of gold and 30,588 ounces of silver. Other properties operating in the Virginia City district, all of which produced gold and silver ore, included the Charles Ray, Easton Pacific, and Mountain Flower mines.

Lead and zinc production predominated in three districts in the county in 1951. In the McCarthy Mountain district, C. O. Dale & Sons worked the Rolly Jane and Bessie mine until November and shipped 277 tons of lead smelting ore containing 6 ounces of gold, 1,924 ounces of silver, 403 pounds of copper, 82,650 pounds of lead, and 7,553 pounds of zinc. A total of 67 tons of lead ore containing approximately 38 percent lead and 20 ounces of silver to the ton, was shipped from the Commonwealth mine in the Rochester District. Slightly less than half of the output from the Sheridan district was zinc-lead ore, most of which was recovered from the Toledo Buckeye group by Victoria Mines, Inc.

MINERAL

The western part of Mineral County adjoining Idaho's famed Coeur d'Alene mining region witnessed considerable revival of interest in long-dormant properties in 1951. Nancy Lee Mines, Inc., began production from the lower level of its Nancy Lee mine and recovered 202 tons of lead concentrate from lead ore treated in the company mill. Other important producers in the county were the Amador mine of the Amador Mining Co. in Cedar and Trout Creeks district, the Iron Mountain mine of the Federal Mining & Smelting Co. in the Iron Mountain district, worked by lessees intermittently during the year, and the Last Chance property in the Packer Creek district, worked by the Jupiter Mining Co.

Digitized by Google

MISSOULA

Copper Cliff (Cramer Creek) District.—Linton Mines operated the Blacktail open-pit mine and 500-ton sink-float plant beginning in April 1951 and treated 10,000 tons of lead ore, which yielded 958 tons of lead concentrate.

Other properties in the county that reported production during the year included the Lucky Boy mine in the Elk Creek district and the Charcoal property in the Wallace district.

PARK

Virtually all the production in the county in 1951 came from the open-pit Estelle mine of the McLaren Gold Mines Co., which was worked from June 1 to December 23. A total of 29,000 tons of gold ore was treated in the company 200-ton flotation mill.

SANDERS

Most of the metal production in Sanders County in 1951 came from the Jack Waite mine in the Eagle district, operated throughout the year by the American Smelting & Refining Co. Production totaled 7,124 tons of zinc-lead milling ore and 186 tons of zinc-lead smelting ore. The milling ore, all treated in the 300-ton flotation plant at the property, contained 6,511 ounces of silver, 1,251,800 pounds of lead, 645,800 pounds of zinc and small quantities of gold and copper.

SILVER BOW

Ore production in Silver Bow County in 1951 increased to 3,780,943 short tons, a 12 percent gain over 1950. The output of copper advanced 5 percent, lead 6 percent, and zinc 27 percent, whereas gold and silver production fell off 32 percent and 3 percent, respectively. The total value of the five metals produced was over 34 percent greater than in 1950 and represented 94 percent of the State total value. Table 11 gives the output of the mines in the county, which includes the Summit Valley (Butte) district, in 1947–51 and cumulative total from 1882 to date.

Summit Valley (Butte) District.—Operations of the Anaconda Copper Mining Co. are described in the following abstract from the company 1951 annual report to its stockholders:

> The construction of surface facilities for the Greater Butte Project was substantially completed during the year. The large ore tonnages from this project will be hoisted through the Kelly shaft, now full size to a depth of 1,370 feet and concrete-lined to a point 315 feet below the 600 level. Of the estimated total of 130,000,000 tons of ore in this project, approximately 56,000,000 tons will become available for haulage to the Kelly shaft on the 600 level, 1,300 level and 2,000 level. Underground mine preparation progressed on schedule and initial mining operations by block caving methods will begin in early 1952. Ore production at the rate of 6,000 tons per day is expected by mid-year. This output will be increased as rapidly as possible to an eventual production of 15,000 tons per day of low grade ores averaging about 20 pounds of recoverable copper per ton. Substantial remodeling of the copper concentrator at Anaconda for the treatment of the larger tonnages of Greater Butte Project low-grade ores proceeded on schedule during the year. In addition to this remodeling, a leach-precipitation-float section was constructed.

Digitized by Google

Zinc mine development during the year within the Butte district disclosed substantial additions to ore reserves at the Anselmo, Badger and Lexington mines. A tunnel 8½ by 9 feet, inside measurement, to connect the Alice and Lexington mines with railroad facilities is being driven.

Except for the Nation-wide strike in the non-ferrous metals industry, which closed the plants from August 27th to September 7th, there was no interference with mining and smelting operations. Butte mines maintained production at the maximum rate permitted by available manpower, resulting in an increase of approximately 7 percent in copper and 37 percent in zinc.

Company material treated at the copper concentrator of the Anaconda Copper Mining Co. at Anaconda comprised 1,038,679 tons of copper ore from the main Butte Hill mine (1,105,856 tons in 1950), 67,834 tons of special waste (50,744 tons in 1950), and 17,559 tons from the Greater Butte project. Direct smelting ores totaled 8,967 tons (20,246 tons in 1950) and mine-water precipitates 9,179 tons (5,823 tons in 1950).

Production of zinc-lead ore from the Butte Hill mines of the Anaconda Copper Mining Co. was 1,189,144 tons in 1951 (871,191 tons in 1950) and that from the Butte Hill dumps 955,372 tons (818,445 tons in 1950).

The Emma and Travona mines, operated by the Anaconda Copper Mining Co., produced manganese ore, which was milled to recover manganese concentrates and a zinc-lead middling concentrate. This middling concentrate was further milled to obtain zinc and lead concentrates totaling 16,855 tons from the Emma middling and 1,730 tons from the Travona middling.

Copper smelting ore and silver smelting ore constituted most of the remainder of the district output in 1951. Of the copper ore production, 18,402 tons came from the Bullwhacker claim, and 15,983 tons from the Sarsfield mine. The most important producers of silver smelting ore included the Marget Anne mine with an output of 1,068 tons, and the Magna Charta mine with 140 tons.

TABLE 11.—Production of gold, silver, copper, lead, and zinc in Silver Bow County, Mont., 1947–51, and total, 1882–1951, in terms of recoverable metal

Year	Mines producing	Ore (short tons)	Gold (lode and placer, fine ounces)	Silver (lode and placer, fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)	Total value

Nevada
Gold, Silver, Copper, Lead and Zinc

(MINE REPORT)

By R. B. Maurer and Leona Froehlich

GENERAL SUMMARY

RESPONDING to extraordinary demand for base metals, expansion of open-pit mining during 1951 resulted in a substantial increase in Nevada copper production compared with 1950. However, the output of lead and of zinc, reflecting a dearth of ore which could be developed rapidly and mined economically, fell considerably below 1950. With precious-metal lode mining at a virtual standstill because of unchanged gold and silver prices, gold production waned in 1951, and silver output was the lowest recorded from Nevada mines since 1899. The total value of gold, silver, copper, lead, and zinc recovered from materials sold or treated in 1951 was $41,280,596 compared with $38,181,872 in 1950, a gain of 8 percent, due largely to copper. Production in 1951 was from 199 lode and 12 placer mines, compared with 325 lode and 25 placer mines in 1950.

Comparing 1951 with 1950, the copper output increased 7 percent in quantity and 25 percent in value; zinc decreased 19 percent in quantity but increased 3 percent in value; lead decreased 24 percent in quantity and 3 percent in value; and gold decreased 32 percent and silver 36 percent both in quantity and value. Of the total value of the five metals, copper comprised more than 66 percent, zinc nearly 16 percent, gold 10 percent, lead 6 percent, and silver 2 percent.

White Pine County produced 72 percent of the State total value of the five metals reported from 17 counties in 1951; it was first in output of copper and gold, second in silver, fourth in zinc, and fifth in lead. Lincoln County, in second place with 19 percent of the State total, led in production of silver, lead, and zinc and was second in copper and fourth in gold.

All tonnage figures reported herein are short tons and "dry weight"; that is, they do not include moisture. Yardage figures used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before treatment. The value of metal production has been calculated at the prices shown in table 1.

TABLE 1.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] (per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

[1] Price under authority of Gold Reserve Act of Jan. 31, 1934.
[2] Treasury buying price for newly mined silver, July 1, 1946, to date—$0.9050505 ($0.905 used in 1947 for calculating purposes).
[3] Yearly average weighted price of all grades of primary metal sold by producers. Price in 1947 includes bonus payments by Office of Metals Reserve for overquota production.

TABLE 2.—Mine production of gold, silver, copper, lead, and zinc in Nevada in 1951, by months, in terms of recoverable metal [1]

Month	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)
January	9,536	98,113	4,653	703	1,834
February	8,848	92,672	4,517	625	1,589
March	11,082	87,375	5,048	631	1,511
April	12,678	85,753	5,223	568	1,183
May	12,102	91,788	5,262	633	1,436
June	10,780	84,919	4,350	603	1,415
July	8,872	74,144	3,890	507	1,515
August	10,244	69,029	3,812	559	1,280
September	9,355	70,008	4,072	551	1,352
October	9,916	77,068	5,219	644	1,474
November	8,481	81,922	5,357	627	1,432
December	9,142	68,878	5,071	497	1,422
Total	121,036	981,669	56,474	7,148	17,443

[1] Mine production comprises ore, gravel, or other mineral material sold or treated and metal recovered as natural gold or as bullion from cyanidation or amalgamation and the estimated recoverable metal (or gross metal as indicated) contained in concentrates, ores, tailings, and other mineral materials shipped directly to smelters or sold to ore buyers within the year.

Gold.—Lode mines supplied 75 percent of the State's total gold in 1951 and placer mines 25 percent; but only 28 percent of the lode gold was derived from precious-metal ores and old tailings treated. The decline in lode-gold output began late in 1950 following the rise in prices of strategic metals and minerals—with consequent upsurge in their production—and continued progressively in 1951, when it became evident that no change in the fixed price of gold would be forthcoming. The slump in placer-gold output was largely the result of operating difficulties at Nevada's only bucket-line dredge.

The following six leading gold-producing mines in 1951, listed in order of output, contributed 88 percent of Nevada's output: Kennecott Copper Corp. Ruth pit, Robinson district, White Pine County (copper ore); Round Mountain Gold Dredging Co., Round Mountain district, Nye County (placer); London Extension Mining Co. Goldacres mine, Bullion district, Lander County (gold ore); Consolidated Coppermines Corp. Morris Brooks pit, Robinson district, White Pine County (copper ore); Natomas Co., Battle Mountain district, Lander County (dredging); and Consolidated Coppermines Corp. Ruth pit extension, Robinson district, White Pine County (copper ore).

Digitized by Google

Silver.—The sharp decline in 1951 silver output was significant in that only 18 percent of Nevada lode silver was derived from precious-metal ores, old tailings and slag; base-metal ores treated, except copper ore, had considerably lower silver content than in 1950.

The following five leading silver-producing mines in 1951, listed in order of output, furnished 69 percent of Nevada's output: Combined Metals Reduction Co. Pioche group, Pioche district, Lincoln County (zinc-lead ore); Summit King Mines, Ltd., Summit King group, Sand Springs district, Churchill County (gold-silver ore); Kennecott Copper Corp. Ruth pit, Robinson district, White Pine County (copper ore); Hill & Chiatovich, San Rafael mine, Quartz Mountain district, Nye County (zinc-lead and lead ores); and Copper Canyon Mining Co. Copper Canyon mine, Battle Mountain district, Lander County (zinc-lead ore).

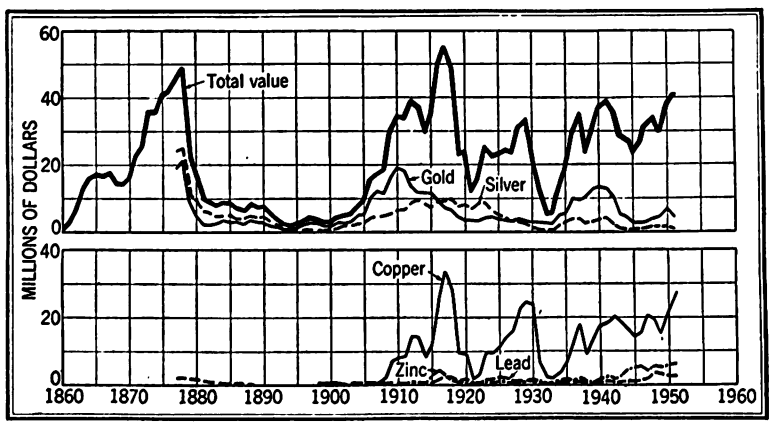

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc in Nevada, 1860–1951.

Copper.—The Robinson district, White Pine County, continued to be Nevada's main source of copper produced; the Kennecott Copper Corp. Ruth and Kimbley pits and Consolidated Coppermines Corp. Morris Brooks pit and Ruth pit extension furnished a preponderant percentage of the State's 1951 output; Kennecott Copper Corp. began development of its Ruth underground mine. Elsewhere in Nevada copper produced was largely a byproduct metal; those small properties that mined straight copper ore failed to develop reserves sufficient to support continuous mining. Anaconda Copper Mining Co. planned immediate development of the Yerington mine, Yerington district, Lyon County, a property with large known reserves of low-grade copper ore.

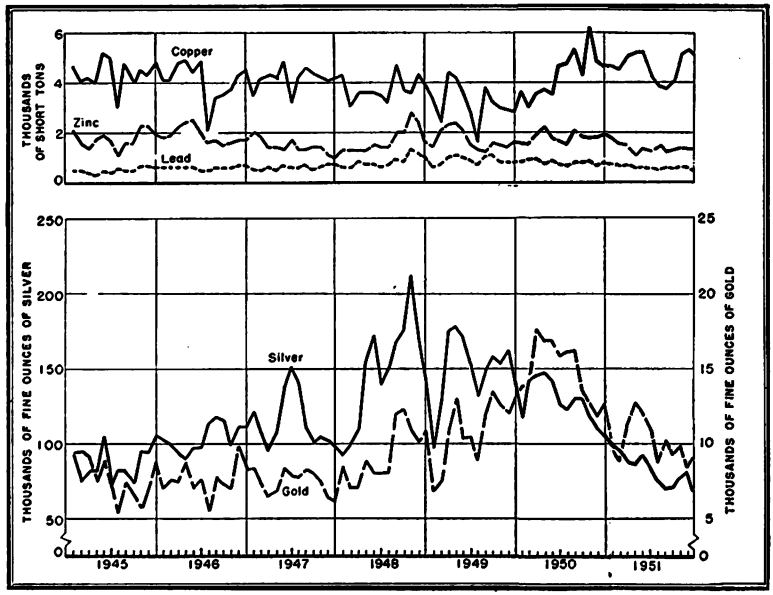

FIGURE 2.—Mine production of gold, silver, copper, lead, and zinc in Nevada, 1945–51, by months, in terms of recoverable metal.

Lead.—The 10-percent increase in lead from straight lead ore was overshadowed by the sharp decrease in yield from zinc-lead ore, the principal source of Nevada lead in 1951. Production was largely from relatively small mines; only one property had an annual output exceeding 400 tons of recoverable lead. Of the State's total, 66 percent was mined in the Pioche district, Lincoln County. The leading producers, in order of output, were: Combined Metals Reduction Co. Pioche group, and Ely Valley Mines, Inc., Ely Valley mine, Pioche district, Lincoln County; Hill & Chiatovich, San Rafael mine, Quartz Mountain district, Nye County; Copper Canyon Mining Co. Copper Canyon mine, Battle Mountain district, Lander County; and Bristol Silver Mines Co. Bristol group, Jack Rabbit district, Lincoln County.

Zinc.—With mine development and expansion of metallurgical facilities still in progress during 1951, the Pioche district, Lincoln County—source of 82 percent of Nevada's zinc in 1951—did not attain the 1950 level of output. The acceptance in 1951 by a Utah slag-fuming plant of larger tonnages of oxidized zinc ore from operating mines and the former Metals Reserve Company Clark County stockpile aided materially in preventing a greater slump in the State's yield of recoverable zinc. Leading producers, in order of output, were: Combined Metals Reduction Co. Pioche group and Ely Valley Mines, Inc., Ely Valley mine, Pioche district, Lincoln County; Cardinalli & Frank, Extension mine and Charles Vaccaro, Mountain View mine, Lone Mountain district, Eureka County; and Bristol Silver Mining Co. Bristol group, Jack Rabbit district, Lincoln County.

[1] Excludes itinerant prospectors, "snipers," "high-graders," and others who gave no evidence of legal right to property.
[2] From property not classed as a mine.
[3] Nye County placer combined with that of Lander County to avoid disclosure of individual output.

MINING INDUSTRY

Despite the uncertainties associated with the national emergency, Nevada's large, open-pit mines were expanded to allow a selectivity of ore which resulted in 7½ percent more copper produced in 1951 from virtually the same tonnage of ore that was mined in 1950. Development of the Robinson district, White Pine County, underground mine and the Yerington district, Lyon County, open-pit mine were outstanding in bolstering the State's reserves of copper ore.

Owing to increased freight rates and the paucity of high-grade ore, mines that shipped direct-smelting lead ore in 1951 (some containing zinc recoverable by fuming) were relatively small. Similarly, shippers of oxidized zinc ore were largely limited in output by the requirements of one fuming plant within reasonable shipping range. Principally,

Digitized by Google

mines with metallurgical facilities for producing zinc and lead concentrates or those reasonably near custom mills or concentrator-smelters had mine expansions in progress or projected. Some loss in Nevada base-metal output was occasioned by the nationwide strike at nonferrous metal facilities from August 27 through September 6, 1951. Precious-metal ore mining declined during 1951 to the extent that only one major operation—an open pit—was worked at the close of the year. Of the 12 placer mines that produced gold and silver 1 was worked by bucket-line dredge, 5 by power excavators and washing plants, 1 by underground methods, and 5 by small-scale hand methods.

ORE CLASSIFICATION

Nevada ores sold or treated in 1951 are classified in table 6. Definitions used in ore classification are given in the Gold and Silver chapter of this volume.

TABLE 6.—Mine production of gold, silver, copper, lead, and zinc in Nevada in 1951, by class of ore or other source material, in terms of recoverable metal

Source	Number of mines [1]	Material sold or treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore:							
Dry gold	50	191,211	22,948	5,567	400	7,700	3,900
Dry gold-silver	20	10,757	1,428	124,735	500	5,500	----------
Dry silver	26	2,688	86	32,338	5,300	63,500	6,000
Total	92	204,656	24,462	162,640	6,200	76,700	9,900
Copper	18	6,630,269	59,863	168,242	111,993,100	3,100	300

Zinc	10	[2] 9,729	[2] 24	[2] 15,861	[2] 1,200	[2] 418,600	[2] 4,238,500
Zinc-lead and zinc-lead-copper [3]	40	297,881	4,073	510,648	399,600	11,066,800	30,493,000
Total	108	6,952,220	64,744	792,463	112,457,800	14,170,200	34,874,600
Other "lode" material:							
Old tailings [4]	7	26,312	1,321	12,512	1,400	45,000	----------
Copper precipitates	2	499	----------	----------	482,600	----------	----------
Old slag (silver)	(5)	46	----------	37	----------	4,100	1,500
Total	9	26,857	1,321	12,549	484,000	49,100	1,500
Total "lode" material	199	7,183,733	90,527	967,652	112,948,000	14,296,000	34,886,000
Gravel (placer operations)	12	----------	30,509	14,017	----------	----------	----------
Total, all sources	211	7,183,733	121,036	981,669	112,948,000	14,296,000	34,886,000

[1] Detail will not necessarily add to totals because some mines produce more than one class of material.
[2] Includes 5,892 tons of ore and contained recoverable metal from the former Metals Reserve Company stockpile at Jean, Nev.
[3] Combined to avoid disclosure of individual output.
[4] Metal recovered, by class of old tailings, as follows: gold, 23,465 tons—1,180 ounces of gold, 3,639 ounces of silver; gold-silver, 1,943 tons—114 ounces gold, 3,401 ounces silver, 2,100 pounds lead; silver, 902 tons—23 ounces gold, 5,451 ounces silver, 1,400 pounds copper, 42,600 pounds lead; lead, 2 tons—4 ounces gold, 21 ounces silver and 300 pounds lead.
[5] From property not classed as a mine.

METALLURGICAL INDUSTRY

Although the percentage of lode material treated at mills remained virtually the same as 1950, the number of Nevada beneficiation plants operated in 1951 was considerably lower than in the previous year owing largely to the decline in precious-metal ore mining. Custom

Digitized by Google

milling of gold and silver ores was confined to treating, at operating mines, occasional lots of ore from small properties, largely as an accommodation. Combined Metals Reduction Co. milled by selective flotation zinc-lead ore on a custom basis for three Nevada mines and company zinc-lead ore at its Caselton mill near Pioche, Lincoln County. This company planned expansion of the existing mill to include facilities both for concentrating oxide ores and producing a manganese concentrate from local ores, some of which contain considerable values in zinc and lead. The rehabilitated Copper Canyon Mining Co. plant was converted to differential flotation during 1951; a bulk concentrate of lead and zinc formerly was produced. The Kennecott Copper Corp. treated all the copper milling ore produced by Consolidated Coppermines Corp. in addition to beneficiating its own ore at the McGill concentrator. Kennecott also operated the McGill copper smelter, Nevada's only smelter, treating in addition to copper materials, gold and silver ores from numerous Nevada mines used for fluxing. The Anaconda Copper Mining Co. Yerington project, Lyon County, included plans for integrated leaching-precipitation facilities at Yerington, Nevada, with eventual smelting and refining of copper precipitates in Montana. Metallurgical data on Nevada ores were published.[1]

REVIEW BY COUNTIES

CHURCHILL

Summit King Mines, Ltd., Sand Springs district, second largest producer of Nevada silver in 1951, closed its Summit King group of mines and cyanide plant in August owing to ore depletion. Mining in other districts was small-scale and sporadic.

CLARK

Activity at zinc and lead mines in the Yellow Pine district was nominal. The Yellow Pine mine (L. F. Jacobson) was the leading producer; 945 tons of ore shipped to lead and fuming plants grossed 10 ounces of gold, 3,223 ounces of silver, 457 pounds of copper, 125,784 pounds of lead and 383,130 pounds of zinc. Metal recovered from 5,892 tons of the former Metals Reserve Company stockpiled oxidized zinc ore treated at a Utah fuming plant augmented the district total. Production of zinc-lead-copper bulk concentrates from low-grade ore at the Herland group, Eldorado Canyon district, by Golden Empire Mining Co., was unprofitable. The company reported an average mining and milling cost of $7.32 per ton. Searchlight Homestake Mining Co. developed the Quartette group, Searchlight district, throughout 1951; 36 tons of sorted ore shipped to a smelter contained 2 ounces of gold, 213 ounces of silver, 4,877 pounds of copper, 1,229 pounds of lead, and 360 pounds of zinc. Principal gold and silver production was from the Quartette and Duplex tailings and Red Bird group ore.

ELKO

Mining zinc-lead and lead ores predominated in 1951, although no important new reserves were reported. Lead production waned in the Delano district; McFarland & Hullinger closed down the Delno mine in January and prospected unsuccessfully for ore at the Cleveland mine. United Minerals Corp. rehabilitated the Rip Van Winkle mine, Merrimac district, shipped some zinc-lead ore to a concentrator-smelter, and initiated an exploration program. Lead & Copper Mines, Inc., worked the Aladdin mine, Railroad (Bullion) district. Activity in the Ruby Range and Spruce Mountain districts was sporadic. The Hicks district was prospected but zinc-lead ore developed was not significant. The Jackson mine (Frank Bullock), Tecoma district, largest producer of Elko County lead, shipped 1,200 tons of direct smelting ore.

ESMERALDA

The slump in gold and silver mining was reflected in overall county output. Although silver production was resumed at the Argentite (Mohawk) mine, Silver Peak district, in a new ore body of undisclosed magnitude, exhausted gold ore reserves closed the Goldfield Deep Mines Co. property in the Goldfield district.

EUREKA

Continued development of the Lone Mountain district oxidized-zinc ore body highlighted activities; 2,325 tons of ore was shipped from the Mountain View and Extension mines to a Utah fuming plant. Pro-

Digitized by Google

duction of lead-zinc ore at the Baldwin mine, Antelope district and Schultes mine, Cortez district was small-scale. Development of the Juniper lead prospect, Union district, was started. Eureka Corp., Ltd., chiefly did maintenance work at the flooded Richmond-Eureka Fad shaft, Eureka district.

HUMBOLDT

Conversion by Getchell Mine, Inc., Potosi district, to tungsten mining and milling deprived the county of its principal precious-metal source. Austin Jumbo Mines, Inc., worked the Austin Jumbo open-pit mine, Awakening district, until November 20; the company reported that amalgamating 50,372 tons of gold ore was unprofitable. The minor base-metal output was from the Pansy Lee mine, Winnemucca (Barrett Springs) district, where both zinc-lead and gold-silver ores were mined.

LANDER

Favorable base-metal prices hastened rehabilitation of the Copper Canyon mine and mill, Battle Mountain district [2], unproductive since the June 1950 shaft fire. A total of 15,740 tons of ore (including test lots of custom ore) grossing 426 ounces of gold, 39,804 ounces of silver, 65,660 pounds of copper, 583,980 pounds of lead, and 358,820 pounds of zinc, was milled. The nearby Iron Canyon mine (Cave Tunnel Lease) and Lucky Strike mine (United Minerals Corp.) were reopened after several inactive years; from the respective mines, 693 and 896 tons of zinc-lead ore were shipped to concentrator-smelters. The London Extension Mining Co. Goldacres open-pit mine, Bullion district, operated throughout the year on low-grade gold ore. Gold output from the Natomas Co. bucket-line dredge at Greenan Placers, Battle Mountain district, fell short of that in 1950, owing to delays occasioned by a slide of tailings into the dredge pond.

LINCOLN

Although still the center of Nevada silver, lead, and zinc production, output of metal from the Pioche and Comet districts fell considerably below 1950. Combined Metals Reduction Co. Caselton mill received 436,824 tons of company (Pioche and Comet groups) and custom ore compared to 452,401 tons in 1950. Significantly, ore from both sources in 1951 was of lower tenor. Ely Valley Mines, Inc., mined virtually the same ore tonnage as 1950, but the grade fell considerably in 1951. Ely Valley mine ore was milled at the company Pioche plant until August, when shipping to a custom mill was resumed. Improvements to expedite ore handling and expansion of ore reserves at Combined Metals Reduction Co. Pioche properties, as well as projected exploration for zinc-lead ore in the company Comet-district properties, and additional concentrating facilities at the Caselton mill for oxide ore were designed to reverse the downward production trend. Bristol Silver Mines Co. worked the Bristol group, Jack Rabbit district, dwindling ore reserves and shipped 1,947 tons of direct-smelting zinc-lead-copper ore while pursuing an intensive exploration program. The Groom mine (Dan Sheahan), Groom district, milled 3,948 tons of lead ore and shipped for direct smelting 563 tons of lead ore.

LYON

Lode mining virtually ceased in 1951. Minor output was reported from the Talapoosa gold-silver mine, Talapoosa district, and from the Mason Valley and McConnell copper properties, Yerington district. Anaconda Copper Mining Co., according to its 1951 annual report, planned to operate the Yerington mine, Yerington district, by open-pit methods in late 1953 at a rate of 60,000,000 pounds of copper per year, which will be increased to an annual rate of 66,000,000 pounds by 1955. The report stated this ore body contains approximately 35,000,000 tons of oxide ore having a grade of 0.97 percent copper available for open-pit mining, beneath which lies at least 15,000,000 tons of sulfide ore of similar grade. Dredging was resumed in the Silver City district by Gus Becker at Dayton and by R. M. Kolze working Carson River tailings. Each operation was a dragline and nonfloating washing plant.

MINERAL

The New Potosi mine (G. A. Peterson and C. A. Wethern, lessee), Candelaria (Columbus) district, which produced 1,218 tons of direct smelting ore grossing 464 ounces of gold, 11,085 ounces of silver, 307 pounds of copper, 196,976 pounds of lead, and 9,632 pounds of zinc throughout 1951, was the only continuous operation.

NYE

Although all large gold and silver lode mines ceased operation before 1951, numerous small properties either milled precious metal ores or shipped flux ore to the Kennecott Copper Co. smelter at McGill, White Pine County. Round Mountain Gold Dredging Corp., Round Mountain district, worked alluvial material by conveyor and stationary mill throughout the year, surpassing the 1950 yield of gold and silver, although operating conditions were difficult technically. The principal base-metal-ore mine was the San Rafael (Hill & Chiatovich), Quartz Mountain district. Formerly worked only for gold, silver, lead, and copper, zinc was encountered in depth, and 285 tons of zinc-lead ore was shipped to a concentrator-smelter in addition to 2,861 tons of direct-smelting lead ore in 1951. Prospects in the Twin River (Millett) and Tybo districts uncovered showings of zinc-lead ore.

ORMSBY

A small development of lead ore at the May mine (A. C. Wilson), Delaware district, was continued in 1951.

PERSHING

Except for token production from a few small mines, precious-metal-ore output was virtually at a standstill. Development of zinc-lead ore at the Antelope group and the extraction of copper concentrate from ore at the Majuba Hill mine, both in the Antelope district, and development of the Little Jupiter mine, Sierra district, gold ore and Silver Star mine, Star district, silver ore, both containing some values in lead and zinc, did not establish important workable base-metal-ore reserves.

Digitized by Google

STOREY

The value of metal produced in 1951 was the lowest recorded in any year since 1859. Attempts by lessees to reopen gold- and silver-producing Comstock district mines were futile, owing to unavailability of custom mills. Central Comstock Mines Corp. closed its gold-silver tailings cyaniding plant in January 1951.

WASHOE

Small gold mines were moderately active in the Olinghouse (White Horse) district. Copper-ore shipments from the Silver Bell mine, Deephole (Granite Range) district, ceased in June 1951.

WHITE PINE

Expansion of copper production in the Robinson district overshadowed other Nevada mining activities in 1951. In exceeding the district 1950 copper output by 8 percent, Kennecott Copper Corp. Nevada Mines Division worked the Ruth (Liberty) pit, continued development of the Kimbley and Wedge test pits, both near Ingersoll Canyon, and initiated development of the Ruth underground property; Consolidated Coppermines Corp. operated its Morris Brooks pit vigorously, and company ore was mined from the Ruth pit extension by arrangement with Kennecott Copper Corp. District zinc and lead output fell compared with 1950. Mines in this category were largely small-scale-lessee-operated; the Columbia group worked by Sam Robison (808 tons of zinc and zinc-lead ore shipped to lead and fuming plants) and the Consolidated Coppermines Corp. Willard lease (329 tons of zinc silicate shipped) led in recoverable metal produced. Exploration was active in the White Pine district, particularly at the Dog Star mine (zinc-lead ore), Onetha mine (lead ore), Seligman mine (zinc-lead ore) and Belmont mine (lead ore). The Grand Deposit mine (lead and copper ores), Aurum district, Bellview mine (lead ore), Chase district, and Good Luck mine (lead ore), Ward district, also were explored, but no important discovery of ore was reported from these districts. County gold and silver output, exclusive of that recovered from base-metal ores, was largely from flux material shipped to smelters.

New Mexico

Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By A. J. Martin

GENERAL SUMMARY

MINE production of gold, silver, copper, lead, and zinc in New Mexico increased in 1951, reflecting the stimulating effect of high base-metal prices and continuous strong consumer demand for the base metals. The output of zinc was the largest in quantity since 1944, gold since 1946, and copper, lead, and silver since 1948. The largest increases over 1950 were 41 percent for lead and 55 percent for zinc; large percentage gains were to be expected for these metals, however, as output in 1950 was unusually low because most of the mines that shut down when metal prices declined in 1949 remained idle several months in 1950. The production of copper—principal metal mined in the State—increased 11 percent in quantity over 1950. The outputs of gold and silver, recovered mostly as byproducts from base-metal ores, increased 16 and 31 percent, respectively. The total value of the five metals, enhanced by the sharp rise in average base-metal prices, reached an all-time high of $54,697,048 compared with $37,437,915 in 1950 and the previous high of $46,799,576 in 1948.

The Central district, Grant County, produced 97 percent of the copper, 92 percent of the zinc, 54 percent of the lead, 53 percent of the silver, and 44 percent of the gold. The total value of the Central district output of these metals was $51,222,739—94 percent of the total value. The yearly production rate of the district in 1951 was still below the full capacity of the equipped mines, as labor strikes kept one important zinc producer idle throughout the year and interrupted operations 2 weeks at several other zinc and zinc-lead mines and the large Chino copper mine.

The Magdalena district, with an output valued at $1,275,971, mostly in zinc and lead, ranked second among New Mexico districts in total value of the five metals; it was followed by the Lordsburg district, with a value of $898,794, mostly in copper, and Hansonberg, with $264,809, nearly all in lead.

All tonnage figures reported herein are short tons and "dry weight"; that is, they do not include moisture. The value of production has been calculated at the prices shown in table 1.

TABLE 1.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] (per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

[1] Price under authority of Gold Reserve Act of Jan. 31, 1934.
[2] Treasury buying price for newly mined silver July 1, 1946, to date—$0.9050505 ($0.905 used in 1947 for calculating purposes).
[3] Yearly average weighted price of all grades of primary metal sold by producers. Price in 1947 includes bonus payments by Office of Metals Reserve for overquota production.

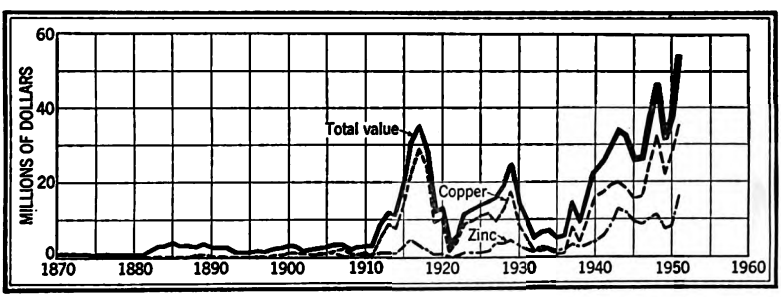

FIGURE 1.—Value of mine production of copper and zinc and total value of gold, silver, copper, lead, and zinc in New Mexico, 1870–1951. The value of gold, silver, and lead produced annually has been relatively small.

Gold.—Of the 3,959 fine ounces of gold produced in New Mexico in 1951, copper ore yielded 45 percent, lead and zinc-lead ores and old tailings 22 percent, zinc ore 17 percent, and gold and silver ores and placer gravel 16 percent. None of the individual mines was a large gold producer; the largest district output was 1,723 ounces from the Central district.

Silver.—The State output of silver in 1951 totaled 443,267 fine ounces compared with 338,581 ounces in 1950. Zinc and zinc-lead

TABLE 2.—Mine production of gold, silver, copper, lead, and zinc in New Mexico in 1951, by months, in terms of recoverable metal [1]

Month	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)
January	247	31,814	6,388	446	3,509
February	254	30,081	6,087	474	3,156
March	283	33,234	5,960	564	3,542
April	489	37,467	6,188	467	3,635
May	332	41,767	6,952	484	4,254
June	424	39,752	6,408	446	4,227
July	389	40,842	6,311	498	4,368
August	510	38,387	4,589	469	3,612
September	202	36,462	4,774	465	3,020
October	244	41,883	6,687	531	4,096
November	371	40,200	6,614	506	4,004
December	214	31,378	6,600	496	3,996
Total	3,959	443,267	73,558	5,846	45,419

[1] Mine production comprises ore, gravel, or other mineral material sold or treated and metal recovered as natural gold or as bullion from cyanidation or amalgamation and the estimated recoverable metal (or gross metal, as indicated) contained in concentrates, ores, tailings and other mineral materials shipped directly to smelters or sold to ore buyers within the year.

ores yielded 69 percent of the total, copper ore and old tailings 26 percent, and lead, gold, gold-silver, and silver ores together 5 percent. The principal producers of silver, in order of output, were the Ground Hog and Bayard zinc-lead mines in Grant County, the Atwood and Bonney-Miser's Chest copper mines in Hidalgo County, and the Lynchburg zinc-lead mine in Socorro County.

Copper.—Production of copper in New Mexico increased from 66,300 short tons in 1950 to 73,558 in 1951. The Chino open-pit mine of the Kennecott Copper Corp. at Santa Rita in the Central district, which produces most of the State output of copper, operated 7 days a week throughout 1951, except during a strike from August 23 to September 6. The Bonney-Miser's Chest underground mine of the Banner Mining Co. in Hidalgo County, a substantial producer of copper, operated continuously. The Atwood mine in Hidalgo County and the Stauber in Guadalupe County (producing low-grade fluxing ore) shipped copper ore direct to the El Paso smelter. About 8,000 tons of old copper-bearing tailings was shipped to the smelter from the old Gillette mill site near Pinos Altos, Grant County. Copper ore and precipitates yielded 99 percent of the total copper in 1951.

TABLE 5.—Mine production of gold, silver, copper, lead, and zinc in New Mexico in 1951, by counties, in terms of recoverable metal

County	Mines producing		Gold (lode and placer)		Silver (all lode)	
	Lode	Placer	Fine ounces	Value	Fine ounces	Value

Digitized by Google

Lead.—Most of the output of lead in 1951 came from mines in the Central and Magdalena districts producing zinc-lead or zinc ore, although a substantial quantity of lead was recovered from lead and lead-barite ores mined in the Hansonberg district, Socorro County. Total production was 5,846 tons compared with 4,150 tons in 1950. Zinc and zinc-lead ores yielded 80 percent of the total, lead ore 18 percent, and other ores and old tailings 2 percent. The larger producers of lead, in order of output, were the Ground Hog and Bayard groups in the Central district and the Lynchburg in the Magdalena district, all producing zinc-lead ore, and the Portales and Mex-Tex lead mines in the Hansonberg district.

Zinc. Despite loss of operating time caused by labor strikes, mines in New Mexico produced 45,419 tons of recoverable zinc in 1951, the largest quantity in any year since 1944. In 1950 the output was only 29,263 tons, as most of the mines that shut down in 1949 because of the drop in the price of zinc remained idle for several months in 1950. In the Central district strikes kept the Hanover mine of the New Jersey Zinc Co., Empire Zinc Division, idle throughout 1951 and interrupted production for 2 weeks at several other mines. Zinc and zinc-lead ores yielded nearly all (99.88 percent) of the State output of zinc in 1951. The Central district contributed 92 percent of the zinc, Magdalena district 5 percent, and other districts 3 percent. The principal producers, in order of output, were the Ground Hog, Oswaldo, Bayard, Kearney, and Pewabic groups, all in the Central district, and the Lynchburg mine in the Magdalena district.

MINING AND METALLURGICAL INDUSTRY

Although the output of recoverable copper in New Mexico in 1951 was 8 percent less than the record high of 80,100 tons produced in 1942, the quantity of copper ore mined (8,024,111 tons) was 5 percent larger than the previous peak of 7,631,752 tons mined in 1942 and 7 percent larger than the 7,510,499 tons mined in 1950. The Chino open-pit mine of the Kennecott Copper Corp. in the Central district, which produced the bulk of the ore, operated 7 days a week throughout 1951, except during a 2-week strike. Other producers included the Bonney-Miser's Chest and Atwood underground mines in the Lordsburg district and the Stauber open-pit mine (producing low-grade fluxing ore) in Guadalupe County. The quantity of zinc, zinc-lead, and lead ores mined totaled 634,016 tons and was the largest since 1944, despite considerable loss of operating time in the Central district caused by strikes. The tonnage of straight gold and silver ores mined was small, as economic conditions continued to be unfavorable for gold mining.

Three New Mexico projects, involving expenditure of $405,055 in combined Government and private capital, had been approved up to December 31, 1951, under the Government program for aiding mineral exploration by matching private funds.

The largest ore-reduction mill in New Mexico is the 22,500-ton Chino concentrator of the Kennecott Copper Corp. at Hurley, Grant County, which treats copper ore from the Chino open-pit mine at Santa Rita. The only smelter operating in the State is the Chino copper smelter, also at Hurley, which treats concentrates from the Chino mill, siliceous copper ore (used as a flux) from the Chino mine,

Zinc	15	548,686	680	228,752	1,374,783	6,270,219	85,293,540
Zinc-lead	21	45,098	290	77,288	137,638	3,058,638	5,436,800
Total	73	8,658,127	2,812	420,697	[2] 109,330,254	11,642,502	90,764,030
Other "lode" material:							
Old tailings, etc.[3]	----	9,119	530	11,344	85,470	45,870	73,970
Copper precipitates [4]	1	22,859	----	----	37,683,606	----	----
Total	1	31,978	530	11,344	37,769,076	45,870	73,970
Total "lode" material	83	8,693,348	3,955	443,267	[2] 147,116,000	11,692,000	90,838,000
Gravel (placer operations)	3	----	4	----	----	----	----
Total, all sources	86	8,693,348	3,959	443,267	[2] 147,116,000	11,692,000	90,838,000

[1] Detail will not necessarily add to totals because some mines produce more than 1 class of ore.
[2] Includes 82,080 pounds of copper contained in 57 tons of copper precipitates recovered from 30,000 tons of newly mined ore treated by heap leaching.
[3] Includes 8,826 tons copper tailings, 36 tons lead mill cleanings, and 257 tons zinc mill cleanings.
[4] Excludes 57 tons of precipitates recovered from newly mined ore treated by heap leaching, copper from which is included under copper ore.

TABLE 7.—Mine production of gold, silver, copper, lead, and zinc in New Mexico in 1951, by method of recovery and type of material processed, in terms of recoverable metal

Method of recovery and type of material processed	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Lode:					
Amalgamation [1]	326	58	----	----	----
Cyanidation [1]	15	----	----	----	----

[2] Includes 8,826 tons copper tailings and 36 tons lead mill cleanings.

Digitized by Google

and copper precipitates from company operations at Chino and at Ray, Ariz. The smelter produces fire-refined copper and some blister copper. Lead and copper concentrates and direct-smelting ores from other New Mexico operations are shipped to smelters in Texas, Arizona, and Illinois. Zinc concentrates are shipped to smelters in Arkansas, Illinois, Montana, Pennsylvania, and Texas.

Mills treating zinc and zinc-lead ores in 1951 comprised the United States Smelting, Refining & Mining Co. 600-ton Bayard mill in the Central district; the Peru Mining Co. 1,000-ton concentrator and the American Smelting & Refining Co. Deming milling unit (capacity recently increased from 400 tons daily to 650 tons) at Deming; and the

[2] Excludes 57 tons obtained from newly-mined ore treated by heap leaching.

REVIEW BY COUNTIES

DONA ANA

The Merrimac mine in the Organ district, operated under lease by Wade White and Ira L. Wright, produced most of the ore shipped from Dona Ana County in 1951. The Defense Department (Air Force) included the site of the mine in the bombing range, and the mine was abandoned in May. The ore contained zinc as the principal mineral, with accessory silver, lead, and copper. The Texas Canyon, Barahoni, and Rickardite mines near Organ shipped some ore. Reports on the Torpedo Copper diamond-drilling research project of the Bureau of Mines at Organ, completed in April 1950, have been published.[1]

GRANT

Central (Bayard, Fierro, Georgetown, Hanover, Santa Rita) District.—The Central district produced copper, zinc, lead, silver, and gold in 1951 valued altogether, in terms of recoverable metals, at $51,222,739, or 94 percent of the State total value of the five metals. From 1904, the first year for which segregated district figures are available, through 1951 the total Central district output of each metal was: Copper, 1,487,760 tons valued at $477,952,492; zinc, 638,753 tons valued at $125,900,118; lead, 86,938 tons valued at $13,511,646; silver, 7,762,426 ounces valued at $4,977,622; and gold, 127,589 ounces valued at $3,296,092—a total value of $625,637,970. The district has also produced a substantial quantity of iron ore.

The large Chino open-pit copper mine of the Kennecott Copper Corp. at Santa Rita operated 7 days a week throughout 1951, except during the August–September strike. A standard-gage railroad with 40 miles of track is used in the pit and on the dumps. Electric shovels handling 8 tons per dip are used on benches for loading broken ore and waste rock; about 45,000 tons of material, about half of which is ore, is generally handled daily, although considerably higher tonnages of waste rock are handled when extensive stripping is required to expand the area of pit operations. The ore is transferred from the

[1] The report of this series for 1929 (chapter of Mineral Resources of the United States, 1929, pt. 1, pp. 729–759) gives the yearly production of each important metal-producing district in New Mexico from 1904 to 1929, inclusive. Subsequent records, year by year, may be found in annual issues of Mineral Resources and Minerals Yearbook.

[2] All from lode mines.

[3] Includes copper recovered from precipitates.

mine railroad to the Atchison, Topeka & Santa Fe Railway branch line on the west side of the pit for delivery to treatment plants at Hurley, 10 miles from the mine. The concentrator has a daily capacity of 22,500 tons. Molybdenite is recovered in the mill as a byproduct. The copper concentrate is smelted in the company smelter adjacent to the mill, which also treats siliceous copper ore used as a flux and precipitates derived from dump leaching. The copper bullion contains minor quantities of gold and silver, which are not recovered from fire-refined copper, the major product of the smelter; the blister copper made contains some recoverable gold and silver.

The Oswaldo zinc mine of the Kennecott Copper Corp. operated throughout 1951 except for the 2-week strike. The ore produced was shipped to custom mills at Deming. Development during the year included 1,448 feet of drifts and 118 feet of raises; the total development in the group at the end of 1951 comprised two vertical shafts 490 and 705 feet deep, 14,796 feet of drifts and crosscuts, and 890 feet

Digitized by Google

of raises. Additional details on development and operation of the mine were published.[2]

The Ground Hog zinc-lead mine of the American Smelting & Refining Co. operated continuously in 1951, except for the strike. The system used in developing and mining the deep ore bodies was described in a recent publication.[3] Since December 1947, two new vertical shafts (the Star and the No. 5) have been sunk, and a 4,400-foot haulageway connecting the shafts on the 1,950-foot level has been excavated. The Star shaft, with four compartments, is 1,926 feet deep, and the No. 5, with three compartments, 2,210 feet deep. The old North shaft is vertical to the 600-foot level and has a winze from there to the 1,800-foot level. Development in 1951 included 8,725 feet of drifts, raises, and crosscuts and 25,870 feet of diamond drilling. The ore produced was shipped over the Atchison, Topeka & Santa Fe Railway branch line to the company Deming milling unit.

The Pewabic mine, operated by the Peru Mining Co., and the Kearney, operated by the New Mexico Consolidated Mining Co. (subsidiary of the Peru Mining Co.), were in production throughout 1951 except during the 2-week strike. The ore produced from both mines was concentrated in the 1,000-ton Peru mill at Deming. Development in the Pewabic group (opened by a 500-foot vertical shaft) in 1951 included 884 feet of drifts and 2,360 feet of diamond drilling. Development in the Kearney mine, opened by a 625-foot vertical shaft, included 2,718 feet of drifts and 6,291 feet of diamond drilling. The Peru Mining Co. also carried on an exploration project in the Grant County mine under a Defense Minerals contract.

The Bayard group of mines of the United States Smelting, Refining & Mining Co. operated continuously in 1951. The group includes the Bull Frog, Hanover-Bessemer, and Shingle Canyon properties. The mining was done by the company and lessees, and the milling by the company in its 600-ton flotation mill at the mine. Development during the year included 7,075 feet of drifts and crosscuts, 2,933 feet of raises, a 78-foot winze, and 18,664 feet of diamond drilling.

Douglas B. White treated by heap leaching 30,000 tons of copper ore mined with bulldozers from an open pit on the Zuniga (United States Smelting) property at Fierro; the yield was 57 tons of precipitates containing 84,623 pounds of copper. Some ore from the Dolomite, Little Goat, and Betty Jo mines and clean-up material from the old Combination mill site were shipped during the year.

The Hanover mine and mill of the New Jersey Zinc Co., Empire Zinc Division, closed by a strike October 17, 1950, remained idle throughout 1951 but were reopened in January 1952.

Other Districts.—There were a number of productive small-scale operations in other districts of Grant County in 1951. At Pinos Altos the Atlas No. 2 mine (Houston Thomas group), operated by Mathis & Mathis, shipped 3,218 tons of zinc-lead-silver ore. From the old Gillette mill tailings dump White & Wright shipped over 8,000 tons of old tailings containing copper, silver, lead, and gold. In the Eureka district Mineral Operations, Inc., continued to operate the Hornet zinc-lead mine and mill on a small scale. In the Steeple Rock district the Alabama and East Camp mines each produced several

[3] Mining World, ASARCO's Star Shaft: Vol. 14, No. 1, January 1952, pp. 26-30.

Digitized by Google

hundred tons of gold-silver ore, and the Carlisle group shipped gold-silver, lead, and zinc-lead ores totaling 1,259 tons. The Royal John mine in the Swartz district shipped zinc-lead-silver ore, and the Grand View and Patsy mines shipped zinc ore.

GUADALUPE

Drunzer & Casner operated the Stauber open-pit mine in the Pintado district 15 miles south of Santa Rosa from January to May and the Pintado in the same district during April; the output was low-grade siliceous copper fluxing ore, shipped to the El Paso smelter.

HIDALGO

Lordsburg District.—The Banner Mining Co. Bonney-Miser's Chest group, principal producer of ore in Hidalgo County since 1936, operated continuously in 1951. The ore was treated in the company 500-ton flotation mill and yielded copper concentrate containing silver and gold. The Atwood mine of C. H. & S. A. McIntosh, operated under lease by Ira L. Moseley, shipped crude copper-silver-gold-lead ore to the El Paso smelter. Other small producers included the Needmore-Homestake, Phoenix, Ruth, and Waldo.

The Silver Hill mine in the San Simon district and the Napane in the Fremont district shipped zinc-lead and lead ore, respectively.

LINCOLN

Two truckloads of lead-silver ore were shipped from the Little Wonder claim in the Red Cloud district and some gold ore was produced from the Old Abe mine at White Oaks.

LUNA

H. E. McCray operated the Mahoney group, including the Surprise (Bryan and Webster claims), in the Cooks Peak district and shipped 2,714 tons of good zinc-lead ore. In the Tres Hermanas district some ore was shipped from the Mahoney, Big Silver, and Measday & Schoepf properties.

At Deming the Peru Mining Co. continued to operate its 1,000-ton selective flotation mill. The bulk of the ore treated came from the Kearney, Pewabic, and Oswaldo mines in the Central district, but the mill continued to treat ore purchased from mine operators in various districts.

The Deming milling unit of the American Smelting & Refining Co. added equipment that increased the daily capacity of the mill from 400 to 650 tons. The mill treated company ore from the Ground Hog mine in the Central district and custom ore from 38 other mines—23 were in New Mexico, 7 in Arizona, 1 in Texas, and 7 in Mexico.

OTERO

E. S. Plumb shipped several cars of copper ore from the Courtney mine in the Sacramento district.

Digitized by Google

SANDOVAL

In the Nacimiento Mountains area the Zia Copper Co. shipped a few cars of low-grade copper ore from the San Miguel mine, and A. D. Miller shipped a little copper-silver ore from one of his claims.

SANTA FE

Near Cerrillos the Tom Payne and Pennsylvania mines each shipped several cars of good zinc-lead-silver ore in 1951. Other small producers included the Grand Central claim near Cerrillos and the Ora Quay and San Pedro groups near Golden.

SIERRA

Some gold was produced from the Snake, Black Peak, El Oro, and Portland claims at Hillsboro and the Lookout in the Tierra Blanca district. Small lots of ore containing base metals were shipped from the Regina and Black Rock claims (Caballos Mountains); Bald Eagle, Dobies, and St. Cloud (at Chloride); and Pelican (Hermosa district).

SOCORRO

Hansonberg District (Bingham).—The Portales Mining Co. operated its open-pit lead mine from February 1 through December. The ore was trucked 33 miles to the company 450-ton mill at San Antonio for treatment. The Mex-Tex Mining Co. shipped 13,967 tons of lead-barite ore from its open-pit mine. The ore was treated in the company 250-ton mill at San Antonio and yielded 321 tons of lead concentrate and 2,804 tons of barite.

Magdalena District.—The Lynchburg mine of the New Jersey Zinc Co., Empire Zinc Division, operated under lease by C. S. Elayer, continued to ship zinc-lead-silver ore to custom mills at Deming. Other producers were the Nitt mine, Waldo group (worked by lessees), Juanita, Queen, and Kelly groups and Bert Coon claim.

TAOS

The D. H. A. Mining Co. shipped 21 tons of copper-silver-gold ore from the Aztec group 8 miles northeast of Dixon.

VALENCIA

The Copper Hill Mining Co. shipped some low-grade copper fluxing ore from the Mirabel claim near Grants.

Oregon

Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By Richard H. Mote

GENERAL SUMMARY

GOLD production in Oregon in 1951 decreased 28 percent below the 1950 output. Silver production decreased 54 percent, copper 42 percent, lead 88 percent, and zinc 86 percent.

Total value of the gold, silver, copper, lead, and zinc (in terms of recoverable metals) produced in Oregon was $290,181 in 1951 compared with $417,765 in 1950, a decrease of 31 percent. The value of the gold produced was 96 percent of the total. Silver value was 2 percent; and combined copper, lead, and zinc values were 2 percent. Baker County continued to be the leading metal producer, supplying 69 percent of the total value. Grant County contributed 20 percent, Lane County 5 percent, and the other 5 producing counties 6 percent.

Placer mines yielded 90 percent and lode mines 10 percent of the gold produced in Oregon in 1951. In 1950 the ratio was placer mines 82 percent and lode mines 18 percent.

Yardage figures used in measuring material treated in placer operations are bank measure; that is, the material is measured in the ground before treatment. The value of metal production reported herein has been calculated at the prices shown in table 1.

TABLE 1.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] (per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

TABLE 2.—Mine production of gold and silver in Oregon in 1951, by months, in fine ounces of recoverable metal [1]

Month	Gold	Silver	Month	Gold	Silver
January	666	1,936	August	568	320
February	493	126	September	590	293
March	690	780	October	390	195
April	697	169	November	330	94
May	831	260	December	291	81
June	1,651	1,477			
July	730	487	Total	7,927	6,218

[1] Mine production comprises ore, gravel, or other mineral material sold or treated and metal recovered as natural gold or as bullion from cyanidation or amalgamation and the estimated recoverable metal (or gross metal as indicated) contained in concentrates, ores, tailings and other mineral materials shipped directly to smelters or sold to ore buyers within the year.

Gold.—Oregon gold production in 1951 decreased 28 percent compared with 1950. Gold output from placer mines was 21 percent below 1950, due mainly to suspension of operations by one of the large bucket-line dredges in July 1951. Over 90 percent of the gold produced in the State was recovered by placer operations. Of the total placer output, 95 percent was recovered by bucket-line dredges, 1 percent by dragline dredges, and the remainder by hydraulic methods, drift mining, and small-scale hand methods.

Gold produced by lode mines decreased 63 percent compared with 1950. The principal producers, which together supplied nearly 88 percent of the gold recovered from lode mines, were the Champion mine in Lane County, the Buffalo mine in Grant County, and the Bourne Group in Baker County.

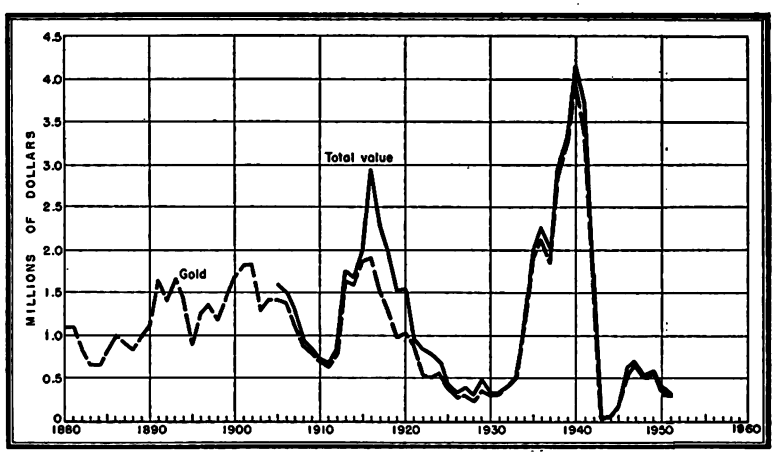

FIGURE 1.—Value of mine production of gold in Oregon, 1880–1951, and total value of gold, silver, copper, lead, and zinc, 1905–51

Digitized by Google

Silver.—Silver production in 1951 decreased 54 percent from 1950. Of the total, 96 percent was produced by three lode mines and two placer mines. These mines, in order of output, were the Buffalo mine (gold ore), Champion mine (gold and zinc-copper ore), Powder River Dredging Co. (bucket-line dredge), Porter & Co. (bucket-line dredge), and the Bourne Group (gold ore).

Copper.—The Champion mine, Lane County, and the Onion Falls mine, Josephine County, were the State's leading copper producers and together furnished 97 percent of the total output. Small quantities of copper were recovered from ores produced from the Bourne Group and from the Buffalo mine.

Lead and Zinc.—The Champion and Buffalo mines were the leading lead and zinc producers in 1951, although neither of these properties was worked continuously during the year.

TABLE 3.—Mine production of gold, silver, copper, lead, and zinc in Oregon, 1947–51, and total, 1852–1951, in terms of recoverable metal [1]

Year	Mines producing [2]		Material sold or treated [3] (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1947	20	49	3,277	18,979	$664,265	30,379	$27,493
1948	23	38	3,119	14,611	511,385	13,596	12,305
1949	28	29	6,215	16,226	567,910	12,195	11,037
1950	32	42	4,257	11,058	387,030	13,565	12,277
1951	14	21	1,495	7,027	277,445	6,218	5,628
1852–1951	----------	----------	(4)	5,760,353	129,575,398	5,301,265	4,863,175

Year	Copper		Lead		Zinc		Total value
	Short tons	Value	Short tons	Value	Short tons	Value	
1947	14	$5,880	12	$3,456	1	$242	$701,336
1948	2	868	7	2,506	----------	----------	527,064
1949	20	7,880	12	3,702	6	1,488	592,107
1950	19	7,904	17	4,590	21	5,964	417,765
1951	11	5,325	2	692	3	1,092	290,181
1852–1951	12,409	4,668,419	798	91,817	172	22,862	139,221,671

[1] Includes recoverable metal content of gravel washed (placer operations), ore milled, and ore shipped to smelters during calendar year indicated.
[2] Excludes itinerant prospectors, "snipers," "high-graders," and others who gave no evidence of legal right to property.
[3] Does not include gravel washed.

[1] Excludes itinerant prospectors, "snipers," "high-graders," and others who gave no evidence of legal right to property.

MINING INDUSTRY

The number of producing lode mines in Oregon declined from 32 in 1950 to 14 in 1951. Most of the operating mines found it impossible to cope with the stabilized price of gold and increased costs of labor, supplies, and transportation. One of the State's larger placer operations was forced to close when its floating washing plant was lost in a flood.

The Bureau of Mines continued its project on investigation of the mineral resources of the Illinois Valley in southwestern Oregon. A number of mineral properties and prospects were examined during the year; several contained gold, silver, copper, lead, and zinc mineralization. Field work for a Bureau of Mines report of investigations on the Takilma-Waldo copper district, Josephine County, Oreg., was completed in April 1951. Results of exploration by trenching, drilling, and investigating mine dumps and accessible workings are set forth in the report which will be published in 1952.

Field teams of the Defense Minerals Administration, made up of Bureau of Mines engineers and geologists of the Geological Survey, examined several Oregon properties for eligibility under the Federal Government's program of assisting the development of domestic mineral resources. As a result of this work, an exploration contract for $30,000 on the Queen of Bronze copper mine, Josephine County, was made with Waite Minerals, Inc., operators of the property.

Copper	1	87	2	32	8,700		
Zinc-copper	1	440	206	918	8,000	2,200	4,200
Total	2	527	208	950	16,700	2,200	4,200
Gravel (placer operations)	21		7,164	1,763			
Total, all sources	35	1,495	7,927	6,218	22,000	4,000	6,000

[1] Detail will not necessarily add to totals because some mines produce more than 1 class of ore.

METALLURGICAL INDUSTRY

Of the 14 lode mines in Oregon in 1951, 7 treated ore by amalgamation, 3 operated concentration mills and shipped the product to smelters (2 also shipped smelting ore), and 4 shipped ore for direct smelting. Over 76 percent of the State total ore was treated in mills, and 24 percent was shipped crude to smelters. The 125-ton flotation mill at the Champion mine near Disston, Oreg., was closed down on June 1, 1951. All crude ore and material requiring smelting was shipped out of the State.

TABLE 7.—Mine production of gold, silver, copper, lead, and zinc in Oregon in 1951, by method of recovery, in terms of recoverable metal

Method of recovery	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Lode: [1]					
Amalgamation	54	10			
Concentration, and smelting of concentrates	471	3,498	8,300	3,800	6,000
Direct smelting	238	947	13,700	200

REVIEW BY COUNTIES

BAKER

In Cracker Creek district, Curl Bourne Mines operated the Bourne Group, 7 miles north of Sumpter, from April through June 1951; 150 tons of crude ore containing 128 ounces of gold, 380 ounces of silver, and 431 pounds of copper was shipped to a smelter. In Sumpter district, the Powder River Dredging Co. worked the Sumpter Valley Placer on Powder River, 3 miles southeast of Sumpter, throughout 1951. The company's electric-powered bucket-line dredge, with 70 9-cubic-foot buckets, washed 2,520,729 cubic yards of gravel, which averaged nearly 8 cents a cubic yard in gold and silver values.

CURRY

A small quantity of gold concentrate was shipped to a mint from the Robert E. mine, in Chetco district, by W. D. Bowser.

DOUGLAS

The Forget-Me-Not mine, in Green Mountain district, was operated for about 3 months during 1951 by L. H. Brooks & Son. C. R. Cleveland operated the Warner mine from August 20 to October 20, 1951. Three tons of selected crude ore containing 25 ounces of gold and 4 ounces of silver was shipped to a smelter.

[1] Only those districts shown separately for which Bureau of Mines is at liberty to publish figures; other producing districts listed in footnote 6 and their output included with "Other districts."
[2] Excludes itinerant prospectors, "snipers," "high-graders," and others who gave no evidence of legal right to property.
[3] Source of silver: 4,455 ounces from lode mines and 1,763 ounces from placers.
[4] Greenhorn district is in Baker and Grant Counties.
[5] From property not classed as a mine.
[6] Includes Sumpter district in Baker County and Granite district in Grant County.

GRANT

Porter & Co. operated a Yuba electric-powered dredge with 60 4½-cubic-foot buckets on the Crane Creek Placers, in Granite district for 3 months in 1951. The Buffalo mine near Granite was operated by R. G. Amidon & Co. during part of the year; 30 tons of concentrate containing 259 ounces of gold, 2,455 ounces of silver, 353 pounds of copper, 1,719 pounds of lead, and 2,001 pounds of zinc and 12 tons of crude ore containing 11 ounces of gold and 110 ounces of silver were shipped to smelters.

The Lucky Strike mine on Greenhorn Mountain, Greenhorn district, was operated during the summer of 1951 by Walter Ross. A small quantity of amalgam was sold to a bullion buyer.

Digitized by Google

JACKSON

The Ashland Mining Co. operated the Ashland mine, Ashland district, during the first part of the year. About 86 tons of ore was milled in the 75-ton amalgamation mill at the mine. Production totaled 10 fine ounces of gold and 6 fine ounces of silver. In Gold Hill district, R. E. Cook and Floyd G. Lance operated the Cook & Lance mine, on Foots Creek 12 miles southwest of Gold Hill, from January through April. About 3,000 cubic yards of bench gravel washed by hydraulic methods yielded 12 ounces of fine gold and 2 ounces of fine silver.

T. Ralph Pittock operated the Pittock mine on West Humbug Creek in Upper Applegate district by hydraulic methods for the first 2 months of the year. The 500 cubic yards of gravel washed yielded 11 fine ounces of gold and 2 of silver. The Apex mine was worked for a short time by J. C. McDonald and the Steamboat Group by Z. J. Collings. Small quantities of gold were produced from both properties.

JOSEPHINE

In Galice district, a dragline dredge, operated by Naron & Vandeventer, Oregon, Ltd., on the Lewis Bar placer during January and part of February, washed 6,500 cubic yards of gravel from which 47 fine ounces of gold and 4 fine ounces of silver were recovered. Operations were discontinued in February when the dredge was lost in a flood. A small quantity of gold was also recovered by small-scale hand methods. The Reno mine, situated one-half mile from the mouth of Whiskey Creek, was worked by Quentin Stone. From 12 tons of ore treated by amalgamation, 26 fine ounces of gold and 3 fine ounces of silver were recovered.

The Goff placer mine, in Greenback district, was worked by Cleo C. Clark during the first 6 months of 1951; 2,000 cubic yards of gravel washed hydraulically yielded 21 fine ounces of gold and 2 of silver. The Onion Falls mine, on Onion Mountain, 30 miles west of Grants Pass in the Illinois River district, was operated for a short time by C. E. Smith, who shipped 87 tons of crude ore to a smelter. Gross metal content of the ore shipped was 2 ounces of gold, 32 ounces of silver, and 8,727 pounds of copper.

LANE

In Bohemia district, the only producing area, Kenneth O. Watkins, lessee, operated the Champion mine, 14 miles southeast of Disston, until June 1, 1951. From about 440 tons of ore milled up to June 1, 39 tons of concentrate was produced and shipped to smelters. The gross metal content of this concentrate was 206 ounces of gold, 918 ounces of silver, 8,808 pounds of copper, 2,516 pounds of lead, and 4,496 pounds of zinc. After June 1 Harold E. L. Barton leased the mine and shipped to a smelter 98 tons of crude ore containing 66 ounces of gold, 402 ounces of silver, 4,720 pounds of copper, and 351 pounds of lead.

South Dakota

Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By Samuel A. Gustavson

GENERAL SUMMARY

SOUTH DAKOTA lode and placer mines in 1951 produced 458,101 fine ounces of gold, 139,590 fine ounces of silver, and 2 short tons of lead with a total value of $16,160,563. Output was reported from five lode mines and three small hand-operated placer mines. In 1950 production was from two lode mines only and totaled 567,996 ounces of gold, 142,065 ounces of silver, and no lead. No copper has been produced since 1944 and no zinc since 1948. Decreases of 19 percent in the output of gold and 2 percent in the output of silver from that of 1950 can be attributed chiefly to a shortage of men for underground mining. Most of the gold and silver was produced from the Homestake mine at Lead, Lawrence County, operated by the Homestake Mining Co. and the Portland, Dakota, and Clinton group of mines operated by the Bald Mountain Mining Co., at Trojan, also in Lawrence County.

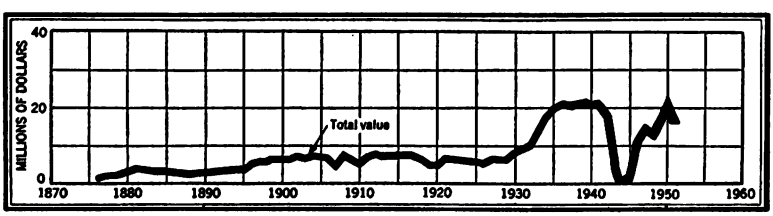

FIGURE 1.—Total value of mine production of gold and silver in South Dakota 1876–1951.

All tonnage figures herein are short tons and "dry weight"; that is, they do not include moisture. The value of production has been calculated at the prices shown in table 1.

MINING AND METALLURGICAL INDUSTRY

Details of mining and milling in South Dakota are given in the following Review by Counties. The tables that follow show the quantity of material treated and the gold and silver recovered by amalgamation and cyanidation. The Homestake Mining Co. treats its ore by both amalgamation and cyanidation, which explains the duplication of tonnage in tables 4 and 5.

TABLE 4.—Gold and silver bullion produced at mills in South Dakota by amalgamation, 1947–51

Year	Material sold or treated (short tons)	Gold in bullion (fine ounces)	Silver in bullion (fine ounces)
1947	849,123	262,257	52,057
1948	896,932	250,782	72,100
1949	1,112,193	312,676	83,538
1950	1,265,118	389,473	111,080
1951	1,046,305	317,593	62,685

TABLE 5.—Gold and silver bullion produced at mills in South Dakota by cyanidation, 1947–51

Year	Material treated (short tons)			Gold in bullion (fine ounces)	Silver in bullion (fine ounces)
	Crude ore	Sands and slimes	Total		
1947	86,511	848,875	935,386	144,888	59,092

REVIEW BY COUNTIES

LAWRENCE COUNTY

Homestake Mine.—The Homestake Mining Co. operated its mine in the Whitewood district through three shafts (the deepest being 4,245 feet) and an inside winze to the 5,000-foot level. Development in the mine during the year included 21,784 feet of drifts, 8,381 feet of raises, and 47,363 feet of diamond drilling. The following data are extracted from the annual report of the general manager of the Homestake Mining Co. for the year ended December 31, 1951:

Ore mined in 1951 was 1,046,203 tons, which compares with 1,265,118 tons in 1950. Bullion with value of $15,486,682.10 was produced. This is $3,777,366.10 less than in 1950. Average realization was $14.80 per ton and metallurgical recovery was 96.79 percent. This compares with $15.23 per ton and 97.03 percent in 1950.

Ore production was 218,915 tons less than in 1950. This reduction resulted entirely from the decrease in the number of men available for underground work. The average number of men employed in the mine department during 1951 was 267 less than in 1950. The shortage of men results primarily from the international situation and the defense production program.

Digitized by Google

Operating expense per ton of ore again increased because of reduced output, increased wage rates and higher supply costs. Such expense, exclusive of taxes and contributions to the Pension Trust was 11.06 per cent higher than in 1950. With inclusion of taxes (except Federal income) and the Pension Trust cost, the 1951 cost was 11.16 per cent higher than in 1950 and 76.47 per cent higher than in 1941.

Broken ore in shrinkage stopes increased from 430,000 tons on December 31, 1950 to 438,600 tons at the end of 1951. The reserve of developed ore, including broken ore, is 20,501,000 tons as compared with 20,804,000 at the end of 1950.

The mine and plant were well maintained and are in excellent condition. Remodelling of the Yates crusher plant with the addition of a third stage of crushing was completed. Operating results are excellent. Completion of similar remodelling of the Ross crusher plant is scheduled for March 1952. With changes in the grinding section of the South Mill, stamps will ultimately be eliminated with resultant economies in operation.

Changes in drilling equipment and practice, resulting from tests which have been carried on for several years, are now being made as rapidly as the material can be obtained. These will result in production economies.

Table 6 presents salient operating data for the Homestake mine for 1947–51.

TABLE 6.—Ore milled, receipts, and dividends, Homestake mine, 1947–51 [1]

Year	Ore milled (short tons)	Receipts for bullion product		Dividends
		Total	Per ton	
1947	849,023	$13,796,720.25	$16.2501	$4,018,560
1948	896,862	12,658,138.55	14.1138	4,018,560
1949	1,112,183	15,683,159.05	14.1012	4,520,880
1950	1,265,118	19,264,048.20	15.2271	5,525,520
1951	1,046,203	15,486,682.10	14.8028	4,319,952

[1] From 1876 to 1951, inclusive, this mine yielded bullion and concentrates that brought a net return of $528,863,881 and paid $175,022,266 in dividends.

Other Mines.—The Bald Mountain Mining Co. operated its Portland, Dakota, and Clinton group of mines (classed as one mine) and 370-ton all-sliming cyanide mill. Ore treated in 1951 totaled 120,051 tons compared with 126,044 in 1950. Gold output decreased 11 percent in 1951; however, silver output increased 38 percent owing chiefly to an increase in the silver content of the ore and to higher mill recovery. Ray Coppo shipped a small quantity of ore containing gold, silver, and lead from the Silver Queen dump.

CUSTER AND PENNINGTON COUNTIES

A small quantity of gold and silver was produced from the Juniper mine operated by the Southern Hills Mines, Inc., and from the Doctor Lode No. 1 and No. 2 by Robert E. Nelson in Pennington County. A few ounces of gold production was recorded from three hand placer operations, one in Custer County and two in Pennington County.

Utah

Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By Paul Luff

GENERAL SUMMARY

DESPITE a strong demand for copper and high prices throughout 1951, Utah's production of copper and gold was less than in 1950, mainly because of a decreased output of copper ore, from which these metals are mostly derived. On the other hand, production of silver, lead, and zinc rose because of increased output of zinc-lead ore, their major source.

Utah remained the second-largest copper-producing State (Arizona was the largest) and ranked second in gold and silver, third in lead, and tenth in zinc.

The value of the five metals in 1951 (exceeded only by that for Arizona) was $182,897,139, the highest in the State's history and 15 percent greater than the value of $159,415,431 in 1950. This increase was due to larger outputs of silver, lead, and zinc and to higher prices for copper, lead, and zinc. Of the total value in 1951, copper contributed 72 percent, lead over 9 percent, gold 8 percent, zinc 7 percent, and silver nearly 4 percent. The value of the metals recovered from copper ore was $146,877,590 in 1951 (80 percent of the State total from all ores), and that recovered from zinc-lead ore was $32,071,468 (18 percent of the State total).

In 1951, 94 percent of Utah's gold production, 65 percent of its silver, over 99 percent of its copper, 54 percent of its lead, and 53 percent of its zinc were recovered from copper ore (including precipitates) and zinc-lead ore from the West Mountain (Bingham) district, Salt Lake County. The remainder of the gold, silver, copper, lead, and zinc was recovered largely from zinc-lead ore and siliceous ores mined in the Park City region and the Tintic district.

All tonnage figures reported herein are short tons and "dry weight"; that is, they do not include moisture. The value of production has been calculated at the prices shown in table 1.

Gold.—Although Utah's 1951 output of recoverable gold (432,216 fine ounces) was 25,335 ounces (6 percent) less than in 1950, it was 23 percent above the annual average of the 10-year period ended with 1950. Most of the gold produced in Utah is a byproduct of copper ore, and since this class of ore declined in 1951 the State's production of gold declined also. In 1951 copper ore yielded 391,400 ounces of

[1] Includes recoverable metal content of gravel washed (placer operations), ore milled, old tailings or slimes retreated, and ore, old tailings, or copper precipitates shipped to smelters during the calendar year indicated.
[2] Does not include gravel washed.
[3] Figures estimated for certain years before 1901.

Digitized by Google

gold—21,690 ounces (5 percent) less than in 1950. Zinc-lead ore supplied 33,489 ounces of gold in 1951, a decrease of 3,835 ounces (10 percent) from 1950. Over 94 percent of the gold recovered from zinc-lead ore came from the Park City region and West Mountain (Bingham) district.

Of the total gold in 1951, 91 percent came from copper ore, 8 from zinc-lead ore, and most of the remainder from silver ore, gold-silver ore, and lead ore; no placer gold was produced in 1951. The West Mountain (Bingham) district supplied 94 percent of the State total, the Park City region 4 percent, and the Tintic district 1 percent. Output of gold in the West Mountain (Bingham) district decreased 5 percent from 1950 and in the Park City region 23 percent, but in the Tintic district it increased 52 percent.

The leading gold producers in Utah in 1951—each with an output exceeding 1,000 ounces of recoverable metal—were as follows: Utah Copper mine and United States & Lark group in the West Mountain

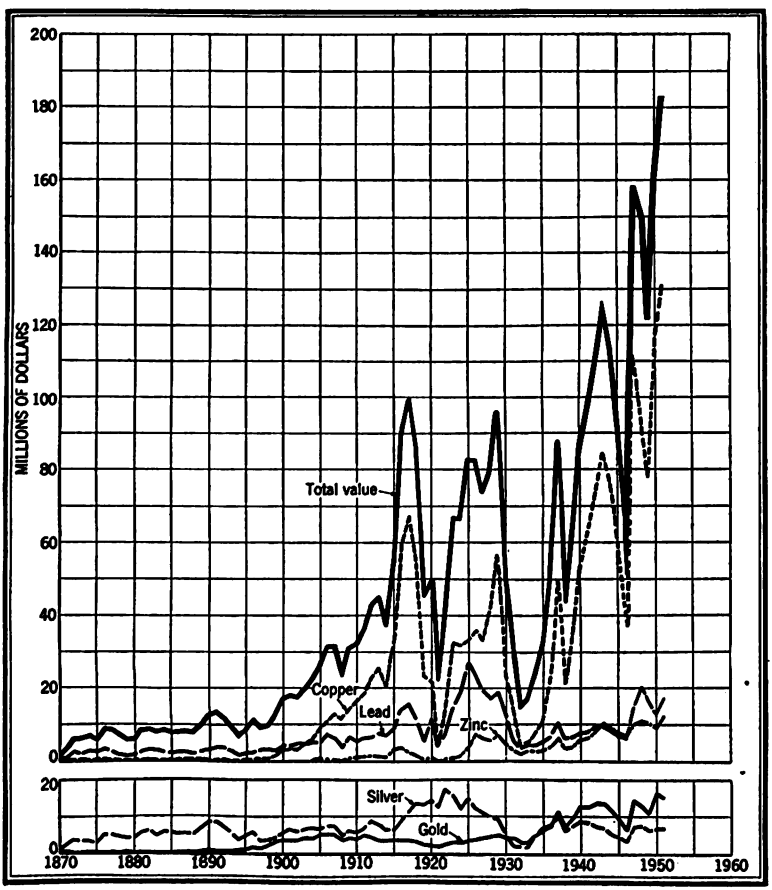

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc, in Utah, 1870–1951.

Digitized by Google

(Bingham) district; the property of the New Park Mining Co. in the Park City region; Chief Consolidated's Chief No. 1 mine in the Tintic district; and Park Utah Consolidated and Silver King Coalition properties in the Park City region. These 6 properties furnished 99 percent of the State gold.

Silver.—Even though Utah's output of recoverable silver increased to 7,310,665 fine ounces in 1951—a 3-percent gain over 1950—it was 7 percent less than the yearly average from 1941 to 1950. A substantial increase in output of silver from zinc-lead ore more than offset the loss in output from copper ore. Copper ore supplied 3,181,269 ounces—131,680 ounces (4 percent) less than in 1950—and zinc-lead ore 3,100,509 ounces—250,835 ounces (9 percent) more than in 1950. About 99 percent of the silver recovered from copper ore came from the West Mountain (Bingham) district, and 92 percent of the silver recovered from zinc-lead ore came from the Park City region, Tintic district, and West Mountain (Bingham) district. Copper ore furnished 44 percent of the State silver in 1951, zinc-lead ore 42 percent, and silver ore and gold-silver ore and old tailings 11 percent; the remainder came principally from lead ore. Output of silver increased 19 percent in the Park City region and 2 percent in the Tintic district but declined 1 percent in the West Mountain (Bingham) district.

Utah properties that produced over 170,000 ounces of recoverable silver each in 1951 were as follows: Utah Copper mine, United States & Lark group, Chief No. 1 mine, and the New Park, Silver King Coalition, Park Utah Consolidated, Butterfield, and Calumet properties. These 8 producers contributed 90 percent of the State silver.

Copper.—Despite a loss of 7,544 short tons (3 percent) in Utah's 1951 output of recoverable copper compared with 1950, the output was 9 percent above the yearly average from 1941 to 1950. The loss resulted from a 6-day shutdown—caused by a strike—at the Utah

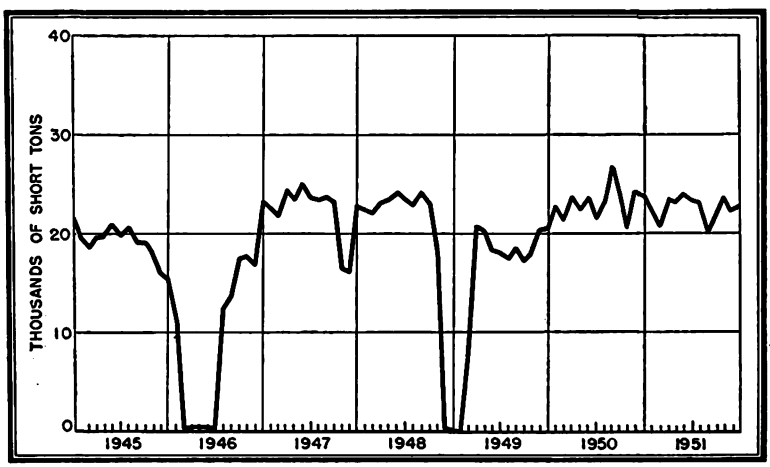

FIGURE 2.—Mine production of copper in Utah, 1945–51, by months, in terms of recoverable metal.

Digitized by Google

Copper property in Bingham Canyon, the State's only large producer. The United States & Lark group, also at Bingham, was the only other Utah property to produce over a million pounds of recoverable copper in 1951. These 2 producers contributed over 99 percent of the State copper.

Lead.—Utah's output of recoverable lead increased to 50,451 short tons in 1951—a gain of 5,698 tons (13 percent) over 1950. The gain resulted mainly from continuous operations, except for brief shutdowns, at the United States & Lark property at Bingham, the largest producer of zinc-lead ore in the State. In 1951 zinc-lead ore from the West Mountain (Bingham) district supplied 27,053 tons of lead (54 percent of the State total), the Park City region 11,297 tons (22 percent), and the Tintic district 2,510 tons (5 percent). The remainder came largely from zinc-lead ore from the Rush Valley (Stockton) and Ophir districts, silver ore and gold-silver ore from the Tintic and West Mountain (Bingham) districts, and lead ore from the West Mountain (Bingham) and Ophir districts. Output of lead in the Park City region was 55 percent more than in 1950 and in the West Mountain (Bingham) district 6 percent more, but in the Tintic district it dropped 15 percent.

The United States & Lark property remained by far the largest producer of lead in Utah, and its output in 1951 was about 10 percent more than in 1950; it was followed by the Chief No. 1, Park Utah Consolidated, Silver King Coalition, New Park, Calumet, Butterfield, Chief Consolidated tailings, Ophir unit of United States Smelting, Refining & Mining Co., and Hidden Treasure properties. These 10 producers supplied 96 percent of the State lead.

Zinc.—Utah's output of recoverable zinc increased to 34,317 short tons in 1951, an 8-percent gain over 1950. The gain resulted mainly from an increased output of zinc-lead ore from the United States & Lark group at Bingham and from the New Park, Park Utah Consolidated, and Silver King Coalition mines in the Park City region. In 1951 zinc-lead ore from the West Mountain (Bingham) district supplied 18,286 tons of zinc (53 percent of the State total); the Park City region contributed 10,209 tons (30 percent) and the Tintic district 3,410 tons (10 percent), nearly all from zinc-lead ore. The remainder came largely from zinc-lead ore from the Ophir and Rush Valley districts and from zinc slag and furnace cleanings from the Smelter (Tooele) district. Production of zinc in the West Mountain (Bingham) district was 13 percent more than in 1950, in the Park City region 37 percent more, and in the Smelter (Tooele) district 98 percent more. Zinc output in the Rush Valley district was about the same as in 1950, but output in the Tintic and Ophir districts dropped 43 and 9 percent, respectively.

The United States & Lark property remained by far the largest producer of zinc in Utah, and its output in 1951 was about 15 percent more than in 1950; it was followed by the Park Utah Consolidated, New Park, Chief No. 1, Silver King Coalition, Butterfield, and Calumet properties, and Tooele old slag and furnace cleanings. These 8 properties furnished 96 percent of the State total zinc.

[1] No placer production in Utah in 1951.
[2] Combined to avoid disclosure of individual company operations.

MINING AND METALLURGICAL INDUSTRY

Utah's mining operations in 1951 were interrupted by strikes for brief periods during the year—a 6-day strike in the copper-mining industry and an 8- to 13-day strike in the zinc-lead-silver-mining industry; in spite of the strike, the quantity of zinc-lead ore mined and treated increased 16 percent (from 579,946 tons in 1950 to 673,022 in 1951), but copper ore decreased 2 percent (from 31,049,641 tons to 30,454,456). Even though the output of copper ore declined in 1951 from 1950, it was well above the average for the 10 years from 1941 to 1950; on the other hand, the output of zinc-lead ore, in spite of an increase over 1950, was below the average for the preceding 10 years. Of the 30,454,456 tons of copper ore produced in Utah in 1951, 30,444,800 tons came from the West Mountain (Bingham) district. Of the 673,022 tons of zinc-lead ore mined in 1951, 373,747 tons (56 percent) came from the West Mountain (Bingham) district, 65,518 tons (10 percent) from the Tintic district, 190,178 tons (28 percent) from the Park City region, 34,871 tons (5 percent) from the Ophir and Rush Valley (Stockton) districts, and 8,708 tons (1 percent)

Digitized by Google

from other districts. Of the 25,593 tons of lead ore mined in 1951, 12,558 tons (49 percent) came from the West Mountain (Bingham) district, 7,890 tons (31 percent) from the Tintic district, 2,237 tons (9 percent) from the Park City region, and 2,908 tons (11 percent) from other districts. Lead slag, smelter cleanings, and old lead tailings treated totaled 3,788 tons. The siliceous material was largely silver ore and old tailings from the Park City region and the Tintic and West Mountain (Bingham) districts. The number of mines producing in the State declined from 86 in 1950 (including 2 placers) to 82 in 1951 (all lode mines).

The driving of a haulage tunnel 21,300 feet long from Bingham to Lark was completed during the year. This tunnel was driven to permit the Kennecott Copper Corp. to extend its open-pit operations toward the southwest. Driving of a new 7,000-foot haulage tunnel was begun during the year 200 feet below the present bottom outlet of the Utah Copper open pit. This tunnel was being driven to minimize haulage adverse to grade as mining operations are extended to lower levels.

During 1951 the Federal Government took steps to stimulate production by aiding in financing exploration projects in search of strategic and critical minerals. In 1951, 17 projects in Utah for copper, lead, zinc, tungsten, and uranium were approved, involving $1,002,752 to be spent by the Federal Government and $895,216 to be spent by private capital. The projects for copper, lead, and zinc were financed on a 50–50 basis, which meant that the Federal Government was to furnish 50 percent of the expense and private capital an equal amount. Repayment of the Government's contribution is to

[1] All lode material; no placer recovery in Utah in 1951.
[2] Detail will not add to totals because some mines produce more than one class of ore.
[3] Gold 570 tons, gold-silver 7,168 tons, silver 43,518 tons, lead 571 tons, zinc 10,000 tons, zinc-lead 38 tons.
[4] Lead slag 2,025 tons, zinc slag 4,881 tons, zinc-lead slag 360 tons, lead smelter cleanings 1,192 tons, zinc smelter cleanings 1,447 tons.

Digitized by Google

be made, without interest, through a royalty on net returns from products sold if ore is discovered or delineated and the ore is mined within 10 years of the date of the contract.

The 31,356,837 tons of ore, old tailings, and other metal-bearing material produced in Utah in 1951 included the following: 31,134,299 tons (99 percent) treated at mills (31,628,415 tons in 1950); 216,210 tons (nearly 1 percent) shipped direct to smelters (223,343 tons in 1950); and 4,881 tons of old slag and 1,447 tons of furnace cleanings smelted and fumed (3,843 tons—all old slag—in 1950).

The 9 mills active in Utah in 1951 treated Utah crude ore as follows: Magna and Arthur concentrators (40,000 tons rated capacity each) of the Kennecott Copper Corp., 30,444,800 tons of copper ore; Midvale 1,700-ton concentrator of the United States Smelting, Refining & Mining Co., Tooele 1,500-ton concentrator of the International Smelting & Refining Co., Park City 800-ton concentrator of the Silver King Coalition Mines Co., Bauer 700-ton concentrator of the Combined Metals Reduction Co., and Horn Silver 500-ton concentrator of the Metal Producers, Inc., 672,432 tons of zinc-lead ore; 1 concentrator in San Juan County treated 6,992 tons of uranium-copper ore and 1 flotation mill in Summit County 10,000 tons of current zinc tailings. The Bauer mill also treated 50 tons of lead ore and 25 tons of zinc ore.

Smelting, milling, and refining operations in Utah were shut down during various periods in 1951, owing to strikes. The Garfield copper smelter of the American Smelting & Refining Co. was idle from July 2 to 29, inclusive; it operated principally on copper concentrates from the Magna and Arthur mills, siliceous crude ore and old tailings from mines and dumps in the Park City region and the Tintic and West Mountain (Bingham) districts, and iron concentrates from the Midvale and Tooele mills. The Midvale lead smelter of the United States Smelting, Refining & Mining Co. was idle for a brief period in August; it operated mainly on lead concentrates and lead ore from company-owned properties in Utah. The Tooele lead smelter of the International Smelting & Refining Co. was idle 6 weeks following a fire in

TABLE 6.—Mine production of gold, silver, copper, lead, and zinc in Utah in 1951, by method of recovery and type of material processed, in terms of recoverable metal

Method of recovery and type of material processed [1]	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)

Digitized by Google

the Cottrell plant August 27; the company zinc-fuming plant, operated in conjunction with the lead smelter, was likewise idle 6 weeks. The lead smelter treated zinc-lead ore, lead ore and concentrates, zinc ore, old zinc slag, and furnace cleanings (zinc) from both company and custom sources. The fuming plant treated 88,374 tons of current hot slag and crude ore in 1951 compared with 87,761 tons in 1950; output in 1951 was 18,084 tons of zinc fume, averaging 74.64 percent zinc and 2.41 percent lead, and 2,056 tons of lead fume averaging 52.61 percent lead and 17.00 percent zinc.

The copper refinery of the Kennecott Copper Corp. and the copper-anode plant of the American Smelting & Refining Co., both at Garfield, operated continuously, except for brief shutdowns caused by strikes. Wire bars are the principal output of the refinery.

ORE CLASSIFICATION

Definitions used in ore classification are given in the Gold and Silver chapter of this volume.

TABLE 7.—Mine production of gold, silver, copper, lead, and zinc in Utah in 1951, by method of recovery and class of material processed, in terms of recoverable metal [1]

REVIEW BY COUNTIES

BEAVER

The principal output in Beaver County in 1951 was zinc-lead ore from the old Horn Silver mine near Milford in the San Francisco district. Metal Producers, Inc., worked the mine most of the year and operated the 500-ton flotation mill 3 months. The mill treated 4,704 tons of zinc-lead ore, which yielded 435 tons of concentrate containing 25 ounces of gold, 7,295 ounces of silver, 8,358 pounds of copper, 154,000 pounds of lead, and 206,754 pounds of zinc. Development of the Harrington-Hickory group near Milford in the Star and North Star district by the Harrington Mines Co. resulted in shipment of 793 tons of ore containing 16 ounces of gold, 7,790 ounces of silver, 5,500 pounds of copper, 99,730 pounds of lead, and 116,469 pounds of zinc. Other county production was 126 tons of copper ore from the Cactus, O. K., and Old Hickory mines, all near Milford.

BOX ELDER

Output in Box Elder County in 1951 was 262 tons of ore containing 52 ounces of silver and 37,032 pounds of copper; the ore was produced by lessees from the Copper Mountain (Salt Lake Copper) group near Montello, Nev., in the Lucin district.

JUAB

Tintic District.—The Tintic district, which lies in both Juab and Utah Counties, is one of the most productive areas in the State. Table 10 gives metal production in each section of the district in 1951, as well as the district total for prior years.

TABLE 10.—Mine production of gold, silver, copper, lead, and zinc in Tintic district, Juab and Utah Counties, Utah, 1947–51, and total, 1869–1951, in terms of recoverable metal

	Mines producing	Ore and old tailings (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)	Total value

Total 1951	15	193,123	4,982	944,818	208	5,553	3,410	4,292,771
Total 1869–1951	----	[1] 15,765,383	2,628,157	264,799,605	123,044	962,814	57,624	416,237,799

[1] Figures estimated for certain years before 1901.

Chief Consolidated Mining Co., in the Juab part of the district, was by far the most important producer in the entire district. The company operated its Chief No. 1 and Eureka Hill mines throughout the year, and the old tailings dump until October 31. According to the company annual report for 1951, the Chief No. 1 mine produced

Digitized by Google

64,136 tons of zinc-lead ore, 36,364 tons of siliceous silver ore, and 8,306 tons of lead-silver ore; and the Eureka Hill mine produced 5,971 tons of lead-silver ore. The ores contained 2,543 ounces of gold, 590,770 ounces of silver, 161,380 pounds of copper, 11,656,032 pounds of lead, and 8,421,975 pounds of zinc. In addition, the company shipped 34,160 tons of old tailings containing 762 ounces of gold, 129,392 ounces of silver, 50,000 pounds of copper, and 1,445,105 pounds of lead. On June 13 the Chief Consolidated Mining Co. signed an exploration contract with the Federal Government, which called for extensive exploration on the 2,700-foot level of the Chief No. 1 mine, sinking a winze 400 feet, and 3,300 feet of workings on the 3,100-foot level.

Lessees worked the American Star mine all year and shipped 10,011 tons of ore containing 456 ounces of gold, 132,380 ounces of silver, 19,000 pounds of copper, 522,614 pounds of lead, and 3,935 pounds of zinc. Lessees worked other properties in the Juab County part of the district; shipments in 1951 comprised 3,456 tons of lead-silver ore from the Centennial-Beck-Victoria group; 2,150 tons of silver ore and 328 tons of gold-silver ore from the Empire group; 1,894 tons of gold-silver ore, 184 tons of zinc-lead ore, and 61 tons of lead ore from the Godiva mine; 79 tons of silver ore from the Plutus mine; and 21 tons of lead ore from the Page and Bonnie Lee claims.

Lessees worked various properties in the Utah County part of the district; shipments in 1951 comprised 11,092 tons of gold-silver ore and 28 tons of zinc-lead ore from the Eureka Standard waste dump; 7,168 tons of old gold-silver tailings and 226 tons of lead tailings from the Harold dump; 2,013 tons of copper-silver ore and 1,814 tons of gold-silver ore from the Eureka Lilly mine; 1,559 tons of gold-silver ore and 68 tons of gold ore from the Mountain View group; 1,197 tons of silver ore from the Tintic Standard waste dump; and 387 tons of gold-silver ore from the Yankee mine.

Other Juab County production included 35 tons of zinc-lead ore from the Little Eva mine, 31 tons of silver ore from the Silver Prince mine, 18 tons of lead-silver ore from the Utah Mine group, and 16 tons of copper ore from the Ibex group.

MILLARD

A few small lots of ore were produced in 1951 from claims in Millard County—10 tons of copper ore from the R. J. Law claim (Detroit district), 11 tons of lead ore from the Blue Bell claim (Gordon district), and 6 tons of lead ore from the Keno claim (Mineral Mountain district).

MORGAN

After being idle for several years, the Carbonate Hill mine near Morgan in the Argenta district was operated in 1951 by lessees who shipped 17 tons of carbonate lead ore.

SALT LAKE

Big and Little Cottonwood Districts.—Output of ore in the Big Cottonwood district declined in 1951, owing largely to the fact that the smelters near Salt Lake City would not accept any carbonate

Digitized by Google

zinc ore from the Cardiff mine after April 13. During the remainder of the year all shipments from this mine were zinc-lead carbonate ore. The Cardiff Mining & Milling Co. reported that a total of 684 tons of zinc ore and zinc-lead ore was shipped from its mine in 1951; the ore contained 3 ounces of gold, 3,654 ounces of silver, 12,216 pounds of copper, 71,790 pounds of lead, and 271,238 pounds of zinc. Lessees worked the South Hecla and Drain Tunnel (Wasatch Mines) properties in the Little Cottonwood district a few months in 1951 and shipped 203 tons of ore containing 5 ounces of gold, 2,159 ounces of silver, 5,061 pounds of copper, 44,634 pounds of lead, and 44,017 pounds of zinc. Other production from the Big and Little Cottonwood districts was 44 tons of lead ore from the American Metal and Lake Blanche properties.

Smelter District.—Output in 1951 comprised 4,325 tons of dump ore and 1,192 tons of smelter cleanings from the Murray smelter site and 2,025 tons of old slag from the Midvale smelter dump.

West Mountain (Bingham) District.—In 1951 the West Mountain (Bingham) district produced 94 percent of the State gold, 67 percent of the silver, over 99 percent of the copper, 58 percent of the lead, and 53 percent of the zinc; the district total value of the 5 metals represented 91 percent of the State total. Output was 30,444,800 tons of copper ore, 373,747 tons of zinc-lead ore, 32,286 tons of siliceous silver ore and gold-silver ore, 12,558 tons of lead ore, and 6,919 tons of copper precipitates. Gold, silver, and copper production in 1951 was less than in 1950, owing mainly to a 6-day shutdown—caused by a strike—at the Utah Copper property. On the other hand, lead and zinc production was greater due to nearly continuous operations of the Lark and U. S. mines of the United States Smelting, Refining & Mining Co.

TABLE 11.—Mine production of gold, silver, copper, lead, and zinc in West Mountain (Bingham) district, Salt Lake County, Utah, 1947–51, and total, 1865–1951, in terms of recoverable metal

Year	Number of mines	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)	Total value
1947	5	29,306,718	384,414	4,816,611	264,315	26,163	20,446	$141,308,766
1948	6	24,889,134	332,588	4,694,674	225,225	30,672	22,077	130,490,268
1949	5	21,405,489	286,155	4,316,378	196,101	32,600	22,311	107,020,080
1950	6	31,405,801	428,313	4,963,586	277,655	27,472	16,120	146,983,284
1951	4	30,863,391	407,196	4,923,249	270,183	29,120	18,286	166,205,080
Total 1865–1951		[1] 661,174,183	7,682,695	166,839,021	5,903,799	1,708,056	578,937	2,494,437,343

[1] Figures estimated for certain years before 1901.

In 1951 the Utah Copper Division of the Kennecott Copper Corp. moved about 45,000,000 tons of waste and treated 30,444,800 tons of ore, averaging 0.957 percent copper, in its two flotation mills at Arthur and Magna, compared with 41,342,160 tons of waste and 31,037,800 tons of copper ore in 1950; the cutoff point between waste and ore was 0.40 percent copper. The two milling plants, which have a combined rated capacity of 80,000 tons of ore a day, operated throughout the year, except for a 6-day shutdown in August. The

Digitized by Google

property is not only the largest producer of copper in the State but in 1951 was again the largest producer of gold and silver in the State and the second-largest producer of molybdenum in the United States.

In 1951 output of zinc-lead ore from the West Mountain (Bingham) district increased to 373,747 tons, a gain of 57,534 tons (18 percent) over that in 1950. This gain resulted from maximum operations nearly all year of the United States & Lark property of the United States Smelting, Refining & Mining Co., the largest producer of zinc-lead ore in the State. Output from both mines in 1951 comprised 355,242 tons of zinc-lead milling ore, 32,247 tons of siliceous silver ore and gold-silver smelting ore, and 12,558 tons of lead smelting ore. Labor supply, especially experienced miners, was short during the summer and fall months, but an aggressive training program and continued mechanization underground maintained operations at both mines at a satisfactory level.

Combined Metals Reduction Co. operated the Butterfield group at Lark nearly continuously and shipped 17,933 tons of zinc-lead ore to the Combined Metals custom flotation mill at Bauer and 39 tons of silver ore to a smelter. The milling ore contained 1,356 ounces of gold, 231,799 ounces of silver, 75,000 pounds of copper, 3,869,601 pounds of lead, and 1,797,793 pounds of zinc.

Other district production was 231 tons of zinc-lead ore from the National Tunnel property and 341 tons of material (zinc-lead) cleaned up from loading stations.

SAN JUAN

Vanadium Corporation of America operated its 20-ton pilot concentrator in White Canyon continuously during the year on uranium-copper ore purchased from various operators.

SUMMIT AND WASATCH

PARK CITY REGION

The Park City region, one of the most productive areas in the State, includes the Uintah district in Summit County and the Blue Ledge and Snake Creek districts in Wasatch County. Table 12 shows the production and total value of the five metals in 1951 compared with 1947-50 and the total from 1870 to 1951.

TABLE 12.—Mine production of gold, silver, copper, lead, and zinc in Park City region, Summit and Wasatch Counties, Utah, 1947–51, and total, 1870–1951, in terms of recoverable metal

Year	Number of mines	Ore and old tailings (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)	Total value
1947	10	657,496	17,052	1,352,748	570	10,987	10,956	$7,875,999
1948	10	506,671	19,087	1,703,864	597	12,670	10,320	9,749,907
1949	10	318,341	19,443	1,061,902	451	8,583	8,359	6,604,858
1950	12	209,640	24,125	952,632	417	7,538	7,425	6,023,922
1951	12	230,607	18,476	1,131,360	470	11,719	10,209	9,668,591
Total 1870–1951	----	[1] 16,307,755	659,989	240,977,206	36,824	1,255,719	390,175	407,107,598

[1] Figures estimated for certain years before 1901.

Digitized by Google

Owing to nearly continuous operations throughout 1951 by all of the principal producers in the Park City region, output of ore and production of each metal (except gold) were greater than in 1950. Output of zinc-lead ore, the chief source of metal production, increased from 120,129 tons in 1950 to 190,178 in 1951, a 58-percent gain. The New Park Mining Co. was the leading producer in the Park City region. The company reported that 88,296 tons of zinc-lead ore was shipped in 1951 compared with 70,480 tons in 1950. The ore in 1951, containing 21,087 ounces of gold, 434,219 ounces of silver, 1,019,881 pounds of copper, 7,737,916 pounds of lead, and 10,985,330 pounds of zinc, was treated in the custom flotation mills of the United States Smelting, Refining & Mining Co. at Midvale and Combined Metals Reduction Co. at Bauer.

The Park Utah Consolidated Mines Co. operated its three units—Judge, Ontario, and Keetley—all year and shipped 55,185 tons (38,231 tons in 1950) of zinc-lead ore to the custom flotation mill of the International Smelting & Refining Co. near Tooele; all ore shipped in 1951 came from the Judge and Keetley units. The ore contained 2,118 ounces of gold, 315,608 ounces of silver, 22,605 pounds of copper, 9,249,384 pounds of lead, and 11,294,400 pounds of zinc. The company announced that results of development in the Ontario mine during 1951 exceeded expectations in the finding of new bodies of ore on all levels.

The 800-ton concentrator of the Silver King Coalition Mines Co. at Park City operated continuously on zinc-lead ore from the company-owned mine in the Uintah district of the Park City region. The company reported that 44,465 tons of ore was milled in 1951, which contained 1,260 ounces of gold, 328,000 ounces of silver, 200,000 pounds of copper, 8,340,000 pounds of lead, and 3,094,000 pounds of zinc. In addition, 1,507 tons of lead-silver ore was shipped direct to a lead smelter in Colorado. The mine produced only 11,418 tons of zinc-lead ore in 1950, as it was operated only 2½ months.

McFarland & Hullinger worked the Ontario waste dump the last 6 months of the year and shipped 18,481 tons of siliceous ore, which contained 362 ounces of gold, 81,366 ounces of silver, 34,458 pounds of copper, and 108,778 pounds of lead. About 10,000 tons of current zinc tailings from the Silver King Coalition mill was re-treated by Reuben Garbett; 2,232 tons of zinc-lead ore from the Silver King waste dump was shipped to custom flotation mills; and 730 tons of lead-silver ore from the Silver King Western mine was shipped direct to a lead smelter. Virtually all the rest of the district output (9,703 tons) was old tailings containing mostly silver and lead shipped from various locations along Silver Creek.

TOOELE

The most productive areas in Tooele County are the Ophir and Rush Valley districts. In 1951, 4 mines in the Ophir district produced 11,395 tons of ore compared with 7,900 in 1950. This gain was due to increased production of zinc-lead ore from the Ophir unit of the United States Smelting, Refining & Mining Co. (from 1,345 tons in 1950 to 8,167 in 1951). McFarland & Hullinger continued to operate the Hidden Treasure mine, but output of lead ore and zinc-lead ore de-

Digitized by Google

clined to 3,054 tons. Other district production was 90 tons of zinc-lead ore from the Mono-Kearsarge group and 45 tons of lead ore and 39 of zinc-lead ore from the Ophir Hill mine.

Output of ore in the Rush Valley district increased from 14,958 tons in 1950 to 26,343 in 1951. Zinc-lead ore produced from the West Calumet mine by the Combined Metals Reduction Co. increased from 6,054 tons in 1950 to 23,420 in 1951, while that from the Honorine mine declined from 8,030 tons to 2,320. The ore from both properties contained 1,632 ounces of gold, 227,644 ounces of silver, 87,500 pounds of copper, 6,060,404 pounds of lead, and 1,995,070 pounds of zinc. Other district production was 570 tons of old tailings, containing chiefly gold and lead shipped by the Combined Metals Reduction Co., and 33 tons of zinc-lead ore produced from the Silver Eagle mine.

The Bar X Mining Co. worked its Esther group in the Erickson district all year and shipped 2,876 tons of ore, which contained 10 ounces of gold, 464 ounces of silver, 4,866 pounds of copper, 380,554 pounds of lead, and 462,560 pounds of zinc. Other county production included 4,881 tons of old zinc slag from the International Smelting & Refining Co. dump near Tooele, 1,447 tons of furnace cleanings from its zinc fuming plant (also near Tooele), 115 tons of zinc-lead ore from the Ida-Desert View group in the Erickson district, 113 tons of copper ore from the Monocco mine in the Clifton (Gold Hill) district, 77 tons of zinc ore and zinc-lead ore from the Four Metals mine and 39 tons of lead ore from the Cannon property in the Dugway district, and 50 tons of lead ore from the Blackhawk claim in the Blue Bell district.

UTAH

American Fork District.—Jay Jacobson shipped 360 tons of old slag, containing principally lead and zinc, from the Yankee property and 113 tons of lead-silver ore from the Dutchman waste dump. Other district production was 60 tons of lead ore from the Blue Rock (Pacific) mine and 11 tons of zinc-lead ore from the Floral lode.

Tintic District.—Mines in the Utah County section of the Tintic district are reviewed under Juab County.

WASATCH

Park City Region.—Mines in the Wasatch County section of the Park City region are reviewed under Summit and Wasatch Counties.

WASHINGTON

The Requa mine in the Harrisburg (Leeds) district was operated a short time in 1951 and produced 52 tons of copper-silver ore. Kentucky-Utah Mining Co. worked the Dixie-Apex mine in the Tutsagubet district most of the year and shipped 111 tons of ore containing 42 ounces of silver, 40,726 pounds of copper, and 630 pounds of lead.

Washington

Gold, Silver, Copper, Lead, and Zinc

(MINE REPORT)

By Richard H. Mote

GENERAL SUMMARY

SUSTAINED high market prices and a brisk demand for metal to meet national defense requirements stimulated mining activity in Washington in 1951 and resulted in all-time high production of ore and recoverable zinc. The output of ore totaled 1,304,495 tons compared with 1,279,595 tons in 1950. Zinc output—over 70 percent of which came from mines in Pend Oreille County—totaled 18,189 tons, a 23-percent increase over the 1950 figure. The production of lead and gold, which had reached new peaks in 1950, declined 23 and 27 percent, respectively, in 1951; copper and silver production also declined.

The total value of the five metals rose to a new record high from $12,652,302 in 1950 to $14,030,884 in 1951, an advance of 11 percent. Expanded production from many of the mines, plus higher average prices for copper, lead, and zinc, were mainly responsible.

Chelan remained in first place among Washington counties in tonnage of ore treated, and Pend Oreille County continued to lead in value of metals produced.

All tonnage figures herein are short tons and "dry weight"; that is, they do not include moisture. The value of the metal production has been calculated at the prices shown in table 1.

Gold.—The decrease of 24,712 ounces in gold output in 1951, compared with 1950, reduced production of the metal in the State to the lowest amount since 1947. This sharp drop resulted mainly from declines in output from the following major producers, listed in order of output: Lovitt Mining Co. Gold King mine, Wenatchee River district, Chelan County; Howe Sound Co. Holden mine, Chelan

TABLE 1.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] (per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

[1] Price under authority of Gold Reserve Act of Jan. 31, 1934.
[2] Treasury buying price for newly mined silver July 1, 1946, to date—$0.9050505 ($0.905 used in 1947 for calculating purposes).
[3] Yearly average weighted price of all grades of primary metal sold by producers. Price in 1947 includes bonus payments by Office of Metals Reserve for overquota production.

Digitized by Google

Lake district, Chelan County; and Knob Hill Mines, Inc., Knob Hill mine, Ferry district, Republic County. These three properties produced nearly 98 percent of the State total gold in 1951.

Silver.—The Knob Hill mine (gold ore) continued to be the leading silver producer in Washington in 1951, followed by the Holden mine (zinc-copper ore). Other important silver producers in 1951, in order of decreasing output, were the Gold King mine (gold ore); the Anaconda Copper Mining Co. Bonanza mine (lead ore), Bossburg

TABLE 2.—Mine production of gold, silver, copper, lead, and zinc in Washington in 1951, by months, in terms of recoverable metal [1]

Month	Gold (fine ounces)	Silver (fine ounces)	Copper (short tons)	Lead (short tons)	Zinc (short tons)
January	6,749	33,964	366	735	1,674
February	5,541	25,198	311	781	1,449
March	6,625	28,830	394	814	1,663
April	3,290	17,903	98	607	1,376
May	5,469	26,292	260	627	1,428
June	7,635	30,123	346	560	1,515
July	5,710	25,096	345	500	1,477
August	4,444	28,573	320	674	1,548
September	4,369	23,591	213	563	1,384
October	5,378	28,763	413	749	1,603
November	7,069	40,402	516	715	1,463
December	5,126	26,213	507	677	1,609
Total	67,405	334,948	4,089	8,002	18,189

[1] Mine production comprises ore, gravel, or other mineral material sold or treated and metal recovered as natural gold or as bullion from cyanidation or amalgamation and the estimated recoverable metal (or gross metal as indicated) contained in concentrates, ores, tailings and other mineral materials shipped directly to smelters or sold to ore buyers within the year.

TABLE 3.—Mine production of gold, silver, copper, lead, and zinc in Washington, 1947–51, and total, 1860–1951, in terms of recoverable metal [1]

Year	Mines producing		Material sold or treated [2] (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1947	25	6	676,176	34,965	$1,223,775	293,736	$265,831
1948	30	1	974,257	70,075	2,452,625	375,831	340,146
1949	29	3	1,012,198	71,994	2,519,790	357,853	323,875
1950	27	6	1,279,595	92,117	3,224,905	363,656	329,127
1951	29	1	1,304,495	67,405	2,359,175	334,948	303,145
1860–1951			[3]	2,515,226	66,788,233	14,555,897	10,671,637

Year	Copper		Lead		Zinc		Total value
	Short tons	Value	Short tons	Value	Short tons	Value	
1947	2,240	$940,800	5,359	$1,543,392	13,800	$3,339,600	$7,313,398
1948	5,665	2,458,610	7,147	2,558,626	12,638	3,361,708	11,171,715

1948				
1949	3	400	10	350
1950	5	1,033	8	280
1951				
Grand total placers:				
1947	6	8,600	77	2,695
1948	1	2,900	10	350
1949	3	400	10	350
1950	6	9,033	39	1,365
1951	1	5,100	13	455

[1] Includes all placer operations using a power excavator and washing plant, both on dry land; an outfit with a movable washing plant is termed a "dry-land dredge."

district, Stevens County; and the Pend Oreille Mines & Metals Co. Pend Oreille mine (zinc-lead ore), Metaline district, Pend Oreille County. These five mines supplied nearly 90 percent of the State total silver.

Copper.—A decline in the output of copper ore at the Holden mine was the principal factor in the 19-percent drop in Washington copper production in 1951. However, despite the smaller ore output, the Holden mine continued to rank first among the State's copper producers and was followed by the Alder Gold-Copper Co. Alder Group mine in Methow district, Okanogan County. These two properties produced over 99 percent of the State copper in 1951.

Lead.—Production of lead in Washington in 1951 decreased 2,332 tons or nearly 23 percent from the record high total of 10,334 tons produced in 1950. This decrease was due mainly to sharp drops in lead production at the Grandview and Bonanza mines. The following mines, ranked in order of decreasing output, were the leading lead producers in the State in 1951: Pend Oreille, Grandview, Bonanza, and Deep Creek. These four properties supplied 98 percent of the State total lead in 1951.

Zinc.—Recoverable zinc production in Washington in 1951 advanced nearly 23 percent over the 1950 output and attained the highest level in the State's mining history. A greatly increased output at the Deep Creek mine and a substantial gain at the property of the Pend Oreille Mines & Metals Co. were the principal factors in establishing the new record output. The leading zinc-producing mines, in order of rank, were: Grandview, Pend Oreille, Deep Creek, and Holden. These four properties produced over 98 percent of the State total zinc in 1951.

MINING INDUSTRY

Washington's mining industry in 1951 was highlighted by expanded activity in mining and development, stimulated largely by the sustained high level in the market prices of copper, lead, and zinc and a strong demand for metals to support the Nation's defense program. Although production was curtailed somewhat by labor shortages reported in several operating areas and the Nation-wide mine, mill, and smelter labor strike from August 27 to September 7, ore output advanced to a new record high level. As compared with 1950, zinc-lead ore production rose 47 percent, while the outputs of gold, lead, zinc, and zinc-copper ores decreased.

Field teams of the Defense Minerals Administration (Defense Minerals Exploration Administration after August 28, 1951, as a result of an Executive order), made up of Bureau of Mines engineers and geologists of the Geological Survey, examined a number of Washington mining properties for eligibility under the Federal Government program of assisting in the exploration of unknown or undeveloped sources of strategic and critical minerals and metals. As a result of this activity, nine exploration contracts totaling $307,646 were approved for properties producing copper, lead, and zinc.

Field work for a Bureau of Mines report of investigations on the Sunset copper deposit in the Index district, Snohomish County, was completed in February 1951. Results of exploration by diamond drilling are described in a report scheduled for publication in 1953.

METALLURGICAL INDUSTRY

Of the 1,304,495 tons of lode material sold or treated in 1951, 1,248,019 tons (96 percent) went to mills and 56,476 tons (4 percent) to smelters compared with 97 and 3 percent, respectively, in 1950.

The 12 flotation mills and 1 gravity-concentration mill that treated ores from Washington mines in 1951 had daily capacities ranging from 25 to 2,000 tons. The 2,000-ton mill was that of the Howe Sound Co., Chelan Division, in Chelan County. The name and location of all the mills and the source of the ore treated are given in the following review by counties and districts.

New milling plants were being constructed during the year at several mining properties in the State. Erection of a 1,000-ton zinc-lead concentrator was begun by the American Smelting & Re-

TABLE 7.—Mine production of gold, silver, copper, lead, and zinc in Washington in 1951, by method of recovery and type of material processed, in terms of recoverable metal

Method of recovery and type of material processed	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)

fining Co. at its Van Stone property in Stevens County, and the Pend Oreille Mines & Metals Co. expected to complete a second 800-ton milling unit early in the second quarter of 1952 at its property in Pend Oreille County. Development of the Advance and Iroquois mines in the Northport district, Stevens County, by Mines Management, Inc., included construction of a 50-ton pilot concentrator.

Most of the ore and concentrates treated in 1951 at the Tacoma electrolytic copper smelter and refinery of the American Smelting & Refining Co. came from Washington mines. Other markets for Washington ores and concentrates during the year included the Bunker Hill & Sullivan Mining & Concentrating Co. lead smelter and refinery at Bradley, Idaho; the American Smelting & Refining Co. lead smelter at East Helena, Mont.; the Anaconda Copper Mining Co. electrolytic zinc plant at Anaconda, Mont.; the American Zinc Co. of Illinois zinc plants at Fairmont City and Monsanto, Ill.; the Sullivan Mining Co. electrolytic zinc plant at Kellogg, Idaho; and the Consolidated Smelting & Refining Co. lead and zinc plants at Trail, British Columbia.

REVIEW BY COUNTIES

CHELAN

In Chelan Lake district, the Howe Sound Co. operated its Holden mine and 2,000-ton concentration mill throughout the year but at a reduced rate compared with 1950. Production was curtailed during April and May, when an underground bulkhead broke and lower levels of the mine were flooded. A strike in August and September also contributed to the decline in production. A total of 550,530 tons of zinc-copper ore was treated in 1951; its gross metal content was 24,205 ounces of gold, 117,437 ounces of silver, 8,543,020 pounds of copper, and 5,323,436 pounds of zinc.

Development of the Polepick mine, in Peshastin Creek (Blewett) district, by the Calton Mining Co., lessee, yielded 20 tons of gold ore, which was treated in the company 25-ton gravity-concentration mill. The Lovitt Mining Co., Inc., operated the Gold King mine, in Wenatchee district, throughout 1951 and shipped 56,378 tons of siliceous gold ore containing 26,492 ounces of gold and 33,838 ounces of silver to a smelter.

FERRY

Knob Hill Mines, Inc., operated its mine and 400-ton flotation-cyanidation mill, in Republic (Eureka) district, on gold ore during all of 1951; it treated about 16 percent less ore than in 1950.

Digitized by Google

GARFIELD

The only production was in Snake River district, where Sheldon Bowers operated a ¾-cubic yard dragline shovel and nonfloating washing plant on the WaWaWai placer property until March; activity was discontinued at that time owing to exhaustion of gold-bearing gravel. A total of 5,100 cubic yards of material was washed during the period of operation, which yielded 13 ounces of gold and 2 ounces of silver.

KING

The Northwestern Realty Co. operated the Rainy mine, in Taylor River district, during part of the year and shipped 31 tons of copper ore to a smelter. This was the only production in the county.

OKANOGAN

Kaaba Silver-Lead Mines, Inc., Loomis-Oroville district, operated its Kaaba mine and mill for 9 months in 1951; it shipped 100 tons of lead concentrate recovered from the treatment of a quantity of lead ore in the company 300-ton sink-float-flotation mill. The Alder Group, in Methow district, was worked by the Alder Gold-Copper Co. and 1,546 tons of copper concentrates containing 1,359 ounces of gold, 2,072 ounces of silver, and 268,202 pounds of copper recovered in the company 250-ton flotation mill were shipped to a smelter. A small quantity of gold ore was shipped to a smelter from the Grey Eagle mine, in Myers Creek district.

PEND OREILLE

All county production was in the Metaline district, where the American Zinc, Lead & Smelting Co. operated its Grandview mine and 750-ton flotation mill at capacity throughout 1951, except for a short period when the property was idle as a result of the industry-wide strike. During the year the company began to develop the Lead Hill property, approximately 15 miles from the Grandview mill, and a small tonnage of lead ore, mined by open-pit methods, was trucked to the mill for treatment in the latter part of 1951.

The Sullivan Mining Co., under an operating agreement with the Metaline Mining & Leasing Co., began to develop the Metaline Contact mine. From 3,556 tons of development ore, milled in the Josephine mill of Pend Oreille Mines & Metals Co. in October, 20 tons of lead concentrates and 72 tons of zinc concentrates were recovered and shipped to smelters.

The Pend Oreille Mines & Metals Co. operated its Pend Oreille mines throughout 1951. The scarcity of skilled miners in the area prevented the production of enough ore to keep both of the company mill units in continuous operation, however; as a result, the 600-ton Josephine mill was shut down for several weeks during the year. Construction of the second 800-ton flotation mill unit of the company projected 2,400-ton mill was in progress in 1951, and the unit was expected to begin operation in the second quarter of 1952. Ore treated in 1951 totaled 273,580 tons, an increase of 87,383 tons over the 186,197 tons milled in 1950. Lead concentrates produced totaled

Digitized by Google

3,999 tons and contained 11,877 ounces of silver, 5,799,144 pounds of lead, and 178,958 pounds of zinc; 11,166 tons of zinc concentrate produced contained 4,164 ounces of silver, 246,770 pounds of lead, and 12,771,626 pounds of zinc.

STEVENS

The Bonanza mine, northwest of Colville, Bossburg (Clugston Creek) district, was in operation throughout 1951. On February 9 the Anaconda Copper Mining Co. obtained a purchase option from the Bonanza Lead Co. and operated the property the rest of the year. About 13,700 tons of ore (20,000 tons in 1950) was milled in the 100-ton flotation mill at the mine, and 3,064 tons of lead concentrate was shipped to a smelter.

Lessees operating the Silver Trail mine of the Silver Trail Mining Co., in the same district, milled 600 tons of zinc-lead ore and recovered 7 tons of lead concentrates and 15 tons of zinc concentrates containing 1,614 ounces of silver, 282 pounds of copper, 8,882 pounds of lead, and 12,238 pounds of zinc. Zinc-lead milling ore was produced from the Young America mine. The property was operated during the middle of the year by Young America Mines, Inc., and by the Bonanza Lead Co. during the latter part of 1951. A total of 20 tons of lead concentrate and 35 tons of zinc concentrate was produced and shipped to smelters.

In Northport (Aladdin) district, the Admiral mine of the Admiral Consolidated Mining Co. was operated by lessees until September and then by the company throughout the remainder of the year. In all, 336 tons of zinc concentrates, containing 135 ounces of silver, 10,866 pounds of lead, and 406,166 pounds of zinc was recovered and shipped to a smelter. The Goldfield Consolidated Mines Co. operated its Deep Creek mine throughout 1951 and treated over four times as much ore in the company 300-ton flotation mill as was milled in 1950. The Gladstone Mountain Mining Co. worked its Gladstone Mountain mine during part of the year and shipped 5 tons of lead ore to a smelter.

The Pioneer Mining Co. began open-pit mining at its Long Shot property, in Old Dominion district. A total of 23 tons of ore, containing 1 ounce of gold, 1,284 ounces of silver, 4,130 pounds of lead, and 4,881 pounds of zinc, was shipped to a smelter. A small quantity of ore milled during the year yielded 18 tons of zinc-lead and zinc concentrates.

WHATCOM

In Glacier district, development on the Glacier mine by the Glacier Mining Co. during part of the year yielded 4 tons of copper ore, which was shipped to a smelter. Walter Gourlie operated the Golden Arrow Group, in Slate Creek district, for 4½ months in 1951 and shipped 10 tons of gold ore to a smelter.

Wyoming
Gold, Silver, Copper, and Lead

(MINE REPORT)

By A. J. Martin

WYOMING output of gold in 1951 was 9 fine ounces valued at $315 and that of silver 2 fine ounces valued at $2, all produced in Fremont County in July. No gold or silver was produced in the State in 1950. No copper has been recovered from Wyoming ores since 1946 and no lead since 1945. No Wyoming output of zinc has been recorded.

In 1951 the White Horse Mining Co. shipped 10 tons of ore from the Diana group of gold mines in the Atlantic City district, Fremont County. At the Copper King property in the Silver Crown or Hecla district in Laramie County 22 miles west of Cheyenne, Henry E. Ferguson and Patrick W. Dinneen, Sr., cleaned out 157 feet of shaft and reopened a 600-foot tunnel.

All tonnage figures reported herein are short tons and "dry weight"; that is, they do not include moisture. The value of production has been calculated at the prices shown in table 1.

TABLE 1.—Prices of gold, silver, copper, lead, and zinc, 1947–51

Year	Gold [1] (per fine ounce)	Silver [2] (per fine ounce)	Copper [3] (per pound)	Lead [3] (per pound)	Zinc [3] (per pound)
1947	$35.00	$0.905	$0.210	$0.144	$0.121
1948	35.00	.905+	.217	.179	.133
1949	35.00	.905+	.197	.158	.124
1950	35.00	.905+	.208	.135	.142
1951	35.00	.905+	.242	.173	.182

[1] Price under authority of Gold Reserve Act of Jan. 31, 1934.
[2] Treasury buying price for newly mined silver July 1, 1946, to date—$0.9050505 ($0.905 used in 1947 for calculating purposes).
[3] Yearly average weighted price of all grades of primary metal sold by producers. Price in 1947 includes bonus payments by Office of Metals Reserve for overquota production.

Table 2 shows the annual output of gold and silver in Wyoming from 1947 to 1951 and the total production of gold, silver, copper, and lead from 1867 to 1951.

The copper, which represents about three-fourths of the total value of four metals, was mined in the Copper Mountain district, Fremont County; Encampment district, Carbon County; Hartville district, originally in Laramie County, now in Platte County; and Laramie (Douglas Creek) district, Albany County. About 76 percent of the copper was mined in 1883 and 1899 to 1909.

Digitized by Google

The lead came from the Spring Creek district in Carbon County, the Hurricane district in Crook County, and the Douglas Creek district in Albany County; it was mined in 1932, 1934, 1935, 1942, and 1945.

Although gold was produced from many localities throughout the State, most of the output came from placer and lode mines in the Atlantic City (South Pass) district in Fremont County. Gold has been produced in Wyoming in nearly all the 85 years from 1867 to 1951, but cumulative output was only 80,040 ounces—over half of which was produced before 1890. The yearly production during the 43-year period from 1890 through 1932 averaged only 450 ounces, but with the rise in the world price of gold after the United States went off the gold standard in April 1933 that led to the fixing of the United States mint price (formerly $20.671835 an ounce) at $35 on February 1, 1934, the yearly output rose to an average of 2,905 ounces from 1933 through 1937. From 1938 through 1951 the only substantial production was 1,486 ounces in 1947, nearly all of which came from the Carissa mine in the South Pass district.

All the Wyoming silver output has been recovered as a byproduct from copper, gold, and lead ores and placer gravel.

TABLE 2.—Mine production of gold, silver, copper, and lead in Wyoming, 1947–51, and total, 1867–1951, in terms of recoverable metal [1]

Year	Material [2] (short tons)	Gold (lode and placer)		Silver (lode and placer)		Copper		Lead		Total value
		Fine ounces	Value	Fine ounces	Value	Short tons	Value	Short tons	Value	
1947	6,059	1,486	$52,010	95	$86	-------	----------	-------	-------	$52,096
1948	867	115	4,025	11	10	-------	----------	-------	-------	4,035
1949	[3] 1,800	389	13,615	21	19	-------	----------	-------	-------	13,634
1950	-------	-------	-------	-------	-------	-------	----------	-------	-------	-------
1951	10	9	315	2	2	-------	----------	-------	-------	317
1867–1951	(4)	80,040	1,909,728	74,821	51,914	16,326	$5,684,372	14	$1,486	7,647,500

[1] Includes recoverable metal content of gravel washed (placer operations), ore milled, and ore shipped directly to smelters during the calendar year indicated.
[2] Does not include gravel washed.
[3] Ore milled; recovery was 86 ounces of gold and 3 ounces of silver in amalgamation and cyanidation bullion and 300 ounces of gold and 18 ounces of silver in 35 tons of concentrates smelted.
[4] Figure not available.

PART IV. WORLD REVIEW

Mineral Production of the World, 1950-51

By Berenice B. Mitchell, Pauline Roberts, and Helen L. Hunt

INTRODUCTION

STATISTICAL tables in this chapter present, country by country, the mineral production of the world in 1950–51. The tables are essentially a retabulation, by countries, of the 55 commodity world tables appearing in the various chapters of this volume. The figures are on a mine basis, unless otherwise indicated, except for cement, coke, and steel, which are measured at the processing plant. Coke entries are for coke made at high temperatures (over 1,000° C.) in slot-type or beehive ovens and exclude gashouse or retort coke. Figures marked with an asterisk (*) are estimates.

The statistics in these tables were derived principally from questionnaires sent, in cooperation with the United States Department of State, to the government of each country. Supplementary sources were United States consular reports, the Imperial Institute's Statistical Summary of the Mineral Industry of the British Commonwealth and Foreign Countries, other official publications of various countries, the United Nations Statistical Yearbook, the Year Book of the American Bureau of Metal Statistics, Minerais et Métaux, business magazines, and company reports. Where official data were not available estimates were often supplied by Bureau of Mines commodity specialists.

For lack of comprehensive information, data for the following minerals are excluded: Andalusite, aplite, asphalt, boron, bromine, calcite (optical), calcium chloride (natural), carbon dioxide, clay, diatomite (kieselguhr), dumortierite, emery, garnet (abrasive), gem stones (other than diamonds), germanium, greensand, grindstones, helium, indium, iodine, kyanite, lithium, magnesium compounds (other than magnesite), meerschaum, mineral pigments, monazite, natural gas, natural gasoline, oil shale, olivine, perlite, pumice, quartz crystal, radium, sand and gravel, selenium, sillimanite, sodium salts (other than common salt), stone, strontium, sulfur (byproduct), tellurium, thallium, topaz (industrial), tripoli, uranium, vermiculite, wollastonite, and zirconium. In addition, a few minor geographic areas for which no statistics are available are also omitted from the tabulation; it is believed that no significant quantities of minerals are mined in any of these areas.

BRITISH WEST INDIES

TABLE 1.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951
Gypsum: Jamaica	23,369	[2]
Salt:		
Bahamas	60,960	51,000
Turks and Caicos Islands	60,960	[2]

[1] The following minerals have been produced in recent years, but no current data are available: Leeward Islands, barite and salt; Haiti, salt. Barbados has produced crude petroleum, but no output was recorded in 1950–51.
[2] Data not available.

CANADA

TABLE 2.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950 [2]	1951	Mineral [1]	1950 [2]	1951
Aluminum	360,043	405,600	Mica (sales)	1,760	1,328
Antimony [3]	292	591	Molybdenum	28	95
Arsenic, white	360	1,091	Nickel	112,181	124,527
Asbestos (sales) [4]	794,095	882,866	Peat:		
Barite	70,013	76,674	Agricultural use	68,215	71,538
Beryllium concentrates	[5] 26	[6]	Fuel	53	18
Bismuth, smelter (kilograms) [7]	86,918	106,140	Petroleum, crude (sales, including natural gasoline) (thousand barrels)	29,044	48,097
Cadmium, smelter (kilograms)	384,828	601,878	Phosphate rock	117	----------
Cement, hydraulic (sold or used by producers) (thousand tons)	2,658	2,687	Platinum-group metals (troy ounces):		
Coal (thousand tons):			Platinum	124,571	154,956
Coal	15,364	14,845	Other platinum-group metals	148,741	162,480
Lignite	1,999	2,017	Pyrites, including cupreous pyrites	283,597	[6]
Cobalt [8]	265	430	Salt	779,132	876,542
Coke (thousand tons)	[5] 3,100	3,086	Silver (troy ounces)	23,221,431	24,244,949
Copper:			Talc, pyrophyllite, and soapstone (shipments)	29,578	26,478
Mine	239,685	245,377	Tin (long tons):		
Smelter	216,094	223,227	Mine	356	155
Feldspar (shipments)	32,248	33,224	Smelter	356	155
Fluorspar	58,253	78,870	Titanium concentrates: Ilmenite [9]	3,177	19,235
Fuel briquets	410,219	359,200	Tungsten concentrates (60 percent WO_3 basis)	215	15
Gold (troy ounces)	4,441,227	4,328,931	Zinc:		
Graphite	3,253	1,467	Mine	284,153	309,450
Gypsum	3,429,332	3,563,745	Smelter	185,398	198,290
Iron ore (thousand tons)	3,271	4,297			
Iron and steel (thousand tons):					
Pig iron and ferroalloys	2,253	2,543			
Steel ingots and castings	3,070	3,236			
Lead:					
Mine	150,317	143,193			
Smelter	154,551	147,609			

[1] Magnesium metal and magnesite have been produced in recent years, but no current data are available. Chromite, corundum, manganese ore, and mercury are produced, but no output was recorded in 1950–51.
[2] Revised figures except for asbestos, beryllium concentrates, coke, fuel briquets, steel ingots and castings, lead (smelter), molybdenum, phosphate rock, pyrites, and smelter tin.
[3] Includes antimony content of antimonial lead.
[4] Exclusive of sand, gravel, and stone.
[5] United States imports.
[6] Data not available.
[7] Refined metal plus bismuth content of bullion exported.
[8] Figures comprise Canadian ore processed in Canada and exported (irrespective of year when mined), plus cobalt content of concentrates made at Port Colborne from copper-nickel ore. However, figures exclude the cobalt recovered at Clydach (Wales) from Canadian nickel-copper ores.
[9] Includes titanium slag containing approximately 70 percent TiO_2.

TABLE 7.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Cement, hydraulic (thousand tons)	42	57	Salt	[2] 11,502	12,061
Chromite	[2] 289	1,138	Silver (troy ounces)	339,360	309,857
Gold (troy ounces) [3]	397	7	Zinc, mine	332	6,457
Lead:					
Mine	3,000	3,300			
Smelter	271	60			

[1] Native sulfur has been produced in recent years, but no current data are available. Mica is produced, but no output was recorded in 1950–51.
[2] Revised figure.
[3] Imports into United States.

HAITI

Salt has been produced in recent years, but no current data are available. Bauxite is produced, but no output was recorded in 1950–51.

HONDURAS

TABLE 8.—Mineral production, 1950–51, in metric tons

Mineral	1950	1951	Mineral	1950	1951
Antimony	(1)	(1)	Mercury (flasks)		11
Gold (troy ounces)	36,545	31,216	Salt	4,397	4,650
Lead, mine	[2] 279	454	Silver (troy ounces)	[2] 3,514,556	3,182,254

[1] Less than 0.5 metric ton.
[2] Revised figure.

MEXICO

TABLE 9.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Antimony [2]	5,868	6,824	Lead:		
Arsenic, white	8,987	12,766	Mine	238,078	225,468
Bismuth, in impure bars (kilograms)	263,000	338,000	Smelter	230,831	219,107
Cadmium (kilograms) [3]	689,000	893,000	Manganese ore	32,400	66,100
Cement, hydraulic (thousand tons)	[4] 1,528	1,615	Mercury (flasks)	3,713	8,093
Coal, bituminous (thousand tons)	[4] 912	1,119	Petroleum, crude (thousand barrels)	72,443	77,312
Coke (thousand tons)	392	389	Silver (troy ounces)	49,141,445	43,797,734
Copper:			Tin (long tons):		
Mine	61,699	67,351	Mine	[4] 440	366
Smelter	48,477	59,241	Smelter	290	366
Fluorspar (exports)	65,667	66,761	Tungsten concentrates (60 percent WO_3 basis)	67	325
Gold (troy ounces)	408,122	394,007	Zinc:		
Graphite	24,626	32,286	Mine	223,530	180,064
Iron ore (thousand tons)	420	460	Smelter	53,492	58,750
Iron and steel (thousand tons):					
Pig iron [5]	249	211			
Steel ingots and castings	[4] 333	[4]430			

[1] Barite, gypsum, mica, salt, and native sulfur have been produced in recent years, but no current data are available. Molybdenum is produced, but no output was recorded in 1950–51.
[2] Includes antimony content of antimonial lead.
[3] Cadmium content of flue dust exported for treatment elsewhere; represent in part shipments from stocks on hand.
[4] Revised figure.
[5] Excluding ferroalloy production, for which data are not yet available.

Fluorspar (shipments)	273,524	314,813
Fuel briquets:		
Briquets	2,512,907	2,165,637
Packaged fuel	123,088	108,440
Gold, refinery (troy ounces)	2,288,708	1,894,726
Graphite (amorphous and crystalline)	4,628	6,473
Gypsum	7,432,186	7,861,199
Iron ore (thousand tons)	99,619	118,375
Iron and steel (thousand tons):		
Pig iron and ferroalloys	[2] 60,210	65,805
Steel ingots and castings [4]	87,848	95,435
Lead:		
Mine	[2] 390,838	352,135
Refinery [5]	458,171	376,142
Magnesite	389,536	607,962
Magnesium metal	14,266	37,086
Manganese ore (shipments)	121,971	95,260
Mercury (flasks)	4,535	7,293
Mica (sold or used by producers):		
Block	262	270
Scrap	62,922	65,200
Molybdenum	12,918	17,625
Nickel, refinery [6]	828	686
Peat, agricultural use	118,589	176,370
Petroleum, crude (thousand barrels)	[2] 1,973,574	2,244,529
Phosphate rock (sold or used by producers)	10,418,122	11,273,282
Platinum, placer platinum and from domestic gold and copper refining (troy ounces)	37,855	36,951
Potassium salts (equivalent K_2O)	[2] 1,168,197	1,288,489
Pyrites, including cupreous pyrites	946,108	1,034,104
Salt:		
Rock salt	3,562,738	4,229,449
Other salt	11,523,492	14,102,056
Silver (troy ounces)	42,308,739	39,907,257
Sulfur, native (long tons)	5,192,184	5,278,249
Talc, pyrophyllite, and soapstone (sold by producers)	563,132	577,028
Tantalite-columbite (mine shipments) (pounds)	1,000	925
Tin (long tons):		
Mine	94	88
Smelter [7]	33,118	31,852
Titanium concentrates:		
Ilmenite	424,851	486,099
Rutile	[8]	[8]
Tungsten concentrates (60 percent WO_3 basis) (shipments)	[2] 4,373	5,693
Zinc:		
Mine	565,513	609,195
Smelter	765,176	799,800

[1] Excludes bismuth and vanadium, data for which Bureau of Mines is not at liberty to publish.
[2] Revised figure.
[3] Smelter output from domestic and foreign ores, exclusive of scrap. Production from domestic ores only was as follows: 1950, 826,760 tons; 1951, 844,379.
[4] Data from American Iron and Steel Institute. Excludes production of castings by companies that do not produce steel ingots.
[5] Figures cover lead refined from domestic and foreign ores; refined lead produced from foreign base bullion not included.
[6] Byproduct of electrolytic refining of copper.
[7] Includes production from imported scrap and residues refined on toll.
[8] Figure withheld in order to avoid disclosure of individual company operations.

[1] Production in Government quarries only.
[2] Data not available.

EUROPE

ALBANIA

Production of crude petroleum in Albania totaled 2,800,000 barrels in 1950 and 1,200,000 in 1951. Production of lignite in Albania was estimated at 16,000 metric tons in 1950; data for 1951 are not available. Cement, chromite, and salt have been produced in recent years, but no current data are available.

[1] Aluminum, arsenic, bauxite, bismuth, cement, cobalt, copper, fluorspar, gold, lead, magnesium metal, manganese ore, mercury, potassium salts, pyrites, and zinc have been produced in recent years, but no current data are available. Nickel is produced, but no output was recorded in 1950–51.
[2] Data not available.
[3] Included with West Germany.
[4] Planned production.
[5] Revised figure.
[6] Exclusive of manganiferous iron ore carrying 12 to 30 percent manganese.
[7] Bauxite, bismuth, cobalt, gold, magnesite, magnesium, and mercury have been produced in recent years, but no current data are available. Nickel and phosphate rock are produced, but no output was recorded in 1950–51. Manganese ore has been produced in recent years, but it is too low-grade to be classified as such.
[8] Includes East Germany.
[9] Approximate production.
[10] Includes scrap.
[11] Crude production estimates based on the following calcined figures: 1950, 630,702; 1951, 679,121.
[12] Including 280,959 tons for agricultural use.

TABLE 33.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Antimony	[2] 350	810	Lead:		
Arsenic, white	33	56	Mine	[2] 2,307	4,852
Asbestos	30	(3)	Smelter	2,125	3,890
Barite	20,799	29,399	Magnesite	26,256	63,859
Bauxite	77,448	197,060	Manganese ore	320	2,290
Cement, hydraulic (thousand tons)	352	432	Pyrites, including cupreous pyrites	87,678	181,263
Chromite	12,631	25,333	Salt	102,329	82,434
Coal: Lignite (thousand tons)	[2] 152	191	Silver (troy ounces)	----------	64,300
Gypsum	820	950	Steel ingots and castings (thousand tons)	*26	(3)
Iron ore (exports) (thousand tons)	41	56	Sulfur, native (long tons)	----------	(3)
			Talc and soapstone	2,500	2,623
			Zinc, mine	3,184	6,300

[1] Molybdenum has been produced in recent years, but no current data are available.
[2] Revised figure.
[3] Data not available.

HUNGARY

TABLE 34.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Bauxite	350,000	(2)	Iron and steel (thousand tons):		
Coal (thousand tons):			Pig iron and ferroalloys	*500	*410
Bituminous	1,400	1,600	Steel ingots and castings	1,022	*1,234
Lignite	11,850	14,000	Lead, mine	300	(2)
Fuel briquets	*125,000	*150,000	Peat	*8,000	*8,000
Iron ore (thousand tons)	368	(2)	Petroleum, crude (thousand barrels)	[3] *3,700	*3,500

[1] Aluminum, antimony, arsenic, cement, copper (mine), gold, lead (smelter), manganese ore, salt, and silver have been produced in recent years, but no current data are available.
[2] Date not available.
[3] Revised figure.

ICELAND

Production of peat in Iceland was estimated to be 3,000 metric tons in 1950 and 2,000 in 1951.

IRELAND

TABLE 35.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Barite	4,821	*7,500	Fuel briquets [2]	27,637	*40,000
Cement, hydraulic (thousand tons)	444	(3)	Gypsum	82,668	*100,000
Coal, bituminous and anthracite (thousand tons)	181	184	Peat	*2,680,300	*4,000,000
			Steel ingots and castings (thousand tons)	*16	*16

[1] Phosphate rock has been produced in recent years, but no current data are available.
[2] Data not available.
[3] Including peat briquets.

TABLE 36.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Aluminum	37,070	49,750	Lead:		
Antimony	[2] 679	822	Mine	[2] 38,300	38,738
Arsenic, white	[2] 670	([3])	Smelter	37,469	36,000
Asbestos	21,433	22,651	Magnesite	200	246
Barite	48,142	75,106	Magnesium metal		([3])
Bauxite	153,433	174,274	Manganese ore	16,208	27,743
Cadmium, smelter (kilograms)	[2] 75,000	204,000	Mercury (flasks)	53,346	53,839
Cement, hydraulic (thousand tons)	5,004	5,578	Peat	*150,000	*150,000
Coal (thousand tons):			Petroleum, crude (thousand barrels)	63	136
Bituminous and anthracite	1,030	1,167	Pyrites, including cupreous pyrites	895,459	898,023
Lignite	780	854	Salt:		
Cobalt		([3])	Rock salt	717,158	746,321
Coke (thousand tons)	1,502	2,173	Other salt	651,935	965,652
Copper:			Silver (troy ounces)	[2] 850,998	821,529
Mine	34	172	Sulfur, native, crude (long tons) [4]	209,767	197,382
Smelter	[2] 18	60	Talc and soapstone	[2] 67,616	75,827
Feldspar	14,254	22,630	Tungsten concentrates (60 percent WO_3 basis)	2	6
Fluorspar	31,611	40,838	Zinc:		
Fuel briquets	*10,000	*25,000	Mine	[2] 87,026	100,733
Gold (troy ounces)	10,674	12,089	Smelter	38,119	47,227
Graphite	3,855	4,486			
Iron ore (thousand tons)	442	515			
Iron and steel (thousand tons):					
Pig iron and ferroalloys	[2] 573	1,048			
Steel ingots and castings	2,323	2,992			

[1] Beryl, gypsum, mica, and potassium salts have been produced in recent years, but no current data are available. Molybdenum, nickel, platinum, and tin are produced, but no output was recorded in 1950–51.
[2] Revised figure.
[3] Data not available.
[4] In addition, the following tonnages of ground sulfur rock (30 percent "S") were produced and used as an insecticide: 1950, 15,778 tons; 1951, 22,120 tons.

LUXEMBOURG

TABLE 37.—Mineral production, 1950–51, in metric tons

Mineral	1950	1951	Mineral	1950	1951
Cement, hydraulic (thousand tons)	125	132	Iron and steel (thousand tons):		
Iron ore (thousand tons)	3,845	5,625	Pig iron and ferroalloys	2,499	3,157
			Steel ingots and castings	[1] 2,451	3,077

[1] Revised figure.

MALTA

Production of salt in Malta totaled 1,827 metric tons in 1950 and 3,841 in 1951.

NETHERLANDS

TABLE 38.—Mineral production, 1950–51, in metric tons

Mineral	1950	1951	Mineral	1950	1951
Cement, hydraulic (thousand tons)	593	702	Iron and steel (thousand tons):		
Coal (thousand tons):			Pig iron and ferroalloys	454	525
Bituminous	12,247	12,424	Steel ingots and castings	490	552
Lignite	194	249	Peat	[1] 527,600	641,900
Coke (thousand tons)	2,804	2,973	Petroleum, crude (thousand barrels)	4,897	4,942
Fuel briquets:			Salt	412,570	*473,000
Bituminous coal	[1] 1,049,200	1,062,400	Tin, smelter (long tons)	21,027	20,977

Cadmium, smelter (kilograms)	4,348	3,900	Peat	4,952	4,410
Cement, hydraulic (thousand tons)	[2] 2,522	2,741	Phosphate rock	24,080	22,830
Coal (thousand tons):			Potassium salts (salable) (equivalent K_2O)	152,000	190,000
Bituminous and anthracite	[2] 11,118	11,553	Pyrites, including cupreous pyrites	[2] 1,453,032	1,630,711
Lignite	[2] 1,318	1,497	Salt:		
Coke (thousand tons)	946	995	Rock salt	[2] 308,228	367,809
Copper:			Other salt	901,575	893,297
Mine [5]	[2] 6,171	[6] 6,804	Silver (troy ounces)	[2] 823,831	735,911
Smelter	[2] 5,211	5,836	Sulfur, native (long tons)	[2] 6,800	(4)
Feldspar (quarry) [7]	1,650	800	Talc and soapstone [8]	25,131	36,034
Fluorspar	32,669	54,789	Tin (long tons):		
Fuel briquets	[2] 1,130,362	1,160,542	Mine	*575	*716
Gold (troy ounces)	13,217	12,777	Smelter	[2] 1,597	945
Graphite	[2] 310	284	Titanium concentrates: Ilmenite	637	700
Gypsum	2,251,831	1,821,676	Tungsten concentrates (60 percent WO_3 basis)	[2] 850	2,300
Iron ore (thousand tons)	[2] 2,088	2,316	Zinc:		
Iron and steel (thousand tons):			Mine	*64,000	*74,000
Pig iron and ferroalloys	680	679	Smelter	21,264	21,345
Steel ingots and castings	[2] 807	831			

[1] Beryl, cobalt, molybdenum, and vanadium have been produced in recent years, but no current data are available.
[2] Revised figure.
[3] Including Spanish Morocco.
[4] Data not available.
[5] According to Year Book of American Bureau of Metal Statistics.
[6] Approximate production.
[7] There is some additional production of feldspar, but comparable figures are not available.
[8] Includes steatite as follows: 1950, 13,702; 1951, 22,628.

SVALBARD (SPITZBERGEN)

Production of coal in Svalbard (Spitzbergen) totaled 379,000 metric tons in 1950 and 470,000 in 1951, exclusive of U. S. S. R.-controlled mines.

SWEDEN

TABLE 44.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Aluminum (includes alloys)	[2] 4,038	6,600	Lead:		
Barite	50	(3)	Mine	22,673	15,059
Bismuth (kilograms)	----------	(3)	Smelter	[2] 16,681	9,435
Cement, hydraulic (thousand tons)	[2] 1,936	2,012	Manganese ore	11,847	(3)
Coal, bituminous (thousand tons)	[2] 309	272	Mercury (flasks)	----------	(3)
Cobalt	----------	(3)	Molybdenum	6	(3)
Coke (thousand tons)	72	----------	Peat:		
Copper:			Agricultural use	*100,000	*100,000
Mine	[2] 16,100	14,424	Fuel	*100,000	*250,000
Smelter	16,708	14,968	Phosphate rock (apatite)	2,044	(3)
Gold (troy ounces)	78,866	80,000	Pyrites, including cupreous pyrites	406,800	420,000
Iron ore (thousand tons)	13,927	16,111	Silver (troy ounces)	1,291,656	(3)
Iron and steel (thousand tons):			Talc and soapstone	13,843	(3)
Pig iron and ferroalloys	[2] 837	838	Tungsten concentrates (60 percent WO_3 basis)	362	*500
Steel ingots and castings	[2] 1,437	1,503	Zinc, mine	[2] 37,121	38,000

[1] Arsenic, chromite, feldspar, fluorspar, fuel briquets, graphite, mica, and salt have been produced in recent years, but no current data are available. Nickel is produced, but no output was recorded in 1950–51.
[2] Revised figure.
[3] Data not available.

Steel ingots and castings	16,555	15,889	Zinc:		
			Mine	37	----------
			Smelter	71,418	70,851

[1] Arsenic, bismuth, chromite, and talc have been produced in recent years, but no current data are available. Bauxite (Northern Ireland) and coal (lignite) (Northern Ireland) are produced, but no output was recorded in 1950–51.
[2] Includes witherite.
[3] Data not available.
[4] Revised figure.
[5] Exclusive of bog ore, which is used mainly for purification of gas.
[6] Includes secondary metal.
[7] Includes magnesium alloy.
[8] Intake by smelters.
[9] Includes production from imported scrap.

ASIA

ADEN

Production of salt in Aden totaled 259,972 metric tons in 1950 and 309,186 in 1951.

AFGHANISTAN

Production of coal in Afghanistan totaled 9,000 metric tons in 1950 and 13,000 in 1951. Production of beryllium totaled 7 metric tons in 1950; data for 1951 are not available. Salt and talc have been produced in recent years, but no current data are available.

BAHRAIN ISLAND

Bahrain Island produced 11,016,000 barrels of crude petroleum in 1950 and 10,994,000 in 1951.

BRITISH BORNEO

TABLE 50.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Antimony [2]	2	----------	Petroleum, crude (thousand barrels)	30,958	37,506

Gold (troy ounces)	[2] 689,441	699,000			

[1] Salt has been produced in recent years, but no current data are available.
[2] Revised figure.
[3] Dry weight.

ITALIAN SOMALILAND

The production of salt in Italian Somaliland totaled 1,500 metric tons in 1950 and 2,000 in 1951.

KENYA

TABLE 86.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Asbestos	229	396	Mica	6	1
Corundum	2	(2)	Salt	18,722	19,084
Gold (troy ounces)	22,945	19,765	Silver (troy ounces)	2,586	2,150
Gypsum	610	83	Talc and soapstone	334	337
Magnesite	181	----------			

[1] Beryl and pyrites have been produced in recent years, but no current data are available. Feldspar and graphite are produced, but no output was recorded in 1950–51.
[2] Data not available.

LIBERIA

Production of gold in Liberia totaled 11,025 troy ounces in 1950 and 9,822 in 1951. Production of iron ore was nil in 1950 and 171,000 metric tons in 1951.

LIBYA

Production of salt in Tripolitania was estimated to be 9,000 metric tons in 1950, but no data for 1951 are available. In Cyrenaica no data for salt production in 1950 are available, but it was estimated to be 2,500 metric tons in 1951.

MADAGASCAR

TABLE 87.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Asbestos	1	(2)	Coal, bituminous (thousand tons)	2	5
Beryllium concentrates	486	530	Gold (troy ounces)	1,936	1,951
Cement, hydraulic (thousand tons)	5	5	Graphite	[3] 14,013	18,340
			Mica	[3] 819	958

[1] Iron ore and salt have been produced in recent years, but no current data are available. Corundum is produced, but no output was recorded in 1950–51.
[2] Data not available.
[3] Revised figure.

MAURITIUS

The production of salt in Mauritius totaled 2,606 metric tons in 1950, but no data for 1951 are available.

TABLE 98.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Beryllium concentrates	44	2	Salt	7,413	(2)
Bismuth (kilograms)	3,658	(2)	Tantalite concentrates (pounds)	(3)	(3)
Columbite concentrates (exports) (pounds) [3]	11,413	45,560	Tin, mine (exports) (long tons)	[4] 192	118
Gold (exports) (troy ounces)	[4] 509	223	Tungsten concentrates (60 percent WO_3 basis)	217	220
Mica	(5)	(5)			
Phosphate rock	467	(2)			

[1] Silver has been exported, but no exports were recorded in 1950–51.
[2] Data not available.
[3] Columbite-tantalite concentrates.
[4] Revised figure.
[5] Less than 0.5 ton.
[6] Included in columbite figure.

UNION OF SOUTH AFRICA

TABLE 99.—Mineral production, 1950–51, in metric tons

Mineral [1]	1950	1951	Mineral [1]	1950	1951
Antimony	[2] 8,311	15,858	Lead, mine	[2] 600	900
Asbestos	[2] 79,300	97,402	Magnesite	11,782	18,773
Barite	2,268	2,038	Manganese ore	790,937	758,870
Beryllium concentrates	844	593	Mica	1,371	1,779
Bismuth (in ore) (kilograms)	7,649	3,184	Nickel	843	1,138
Cement, hydraulic (thousand tons)	1,847	1,953	Phosphate rock	51,844	81,840
Chromite	496,324	545,306	Platinum-group metals (troy ounces):		
Coal, bituminous (marketable) (thousand tons)	26,473	26,632	Platinum-group metals from platinum ore	144,217	190,898
Coke (thousand tons) [3]	1,036	[4] 1,200	Osmiridium from gold ores	6,449	6,359
Copper:			Pyrites, including cupreous pyrites	36,026	33,378
Mine	33,982	33,731	Salt	[2] 106,396	149,795
Smelter	33,342	32,922	Silver (troy ounces)	1,119,135	1,162,588
Corundum	3,201	4,563	Talc, pyrophyllite, and soapstone	3,978	5,663
Diamonds (metric carats):			Tantalite concentrates (sales and exports) (pounds)	4,000	6,000
Lode	1,516,194	1,967,272	Tin (long tons):		
Alluvial [4]	231,674	289,063	Mine	[2] 643	746
Feldspar	[2] 6,001	3,343	Smelter	[2] 718	829
Fluorspar	[2] 6,948	12,313	Tungsten concentrates (60 percent WO_3 basis)	96	160
Gold (troy ounces)	11,663,713	11,516,450			
Graphite	244	328			
Gypsum (sales and exports)	103,707	124,979			
Iron ore (thousand tons)	1,189	1,421			
Iron and steel (thousand tons):					
Pig iron and ferroalloys	733	805			
Steel ingots and castings	755	948			

[1] Arsenic, columbite, and mercury are produced, but no output was recorded in 1950–51.
[2] Revised figure.
[3] Revised to include coke production of South African Iron and Steel Corp., Limited (ISCOR).
[4] Includes an estimated 100,000 carats in each year for State mines of Namaqualand.

Feldspar [7]	[2] 13,276	14,328	Titanium concentrates:		
Fluorspar	585	*250	Ilmenite	[8] 12,417	([3])
Fuel briquets [6]	598,010	*590,000	Rutile	[9] 18,379	33,718
Gold (troy ounces)	[2] 868,567	886,170	Tungsten concentrates (60 percent WO_3 basis)	[2] 1,235	1,864
Graphite	[2] 147	129	Zinc:		
Gypsum	[2] 340,151	370,195	Mine	[2] 205,632	197,843
Iron ore (thousand tons)	2,403	2,468	Smelter	[2] 84,995	78,246
Iron and steel (thousand tons):					
Pig iron and ferroalloys	[2] 1,336	1,357			
Steel ingots and castings	[2] 1,448	1,457			
Lead:					
Mine	[2] 222,694	228,407			
Smelter	[2] 163,102	173,767			

[1] Asbestos (Tasmania), corundum (New South Wales), diamonds, and magnesium metal have been produced, but no current data are available. Mercury and placer platinum (New South Wales) are produced, but no output was recorded in 1950–51.
[2] Revised figure.
[3] Data not available.
[4] Preliminary figure.
[5] Partly estimated; excludes content of some bismuth-tungsten concentrates.
[6] Fiscal year ended June 30 of year stated.
[7] Includes some china stone.
[8] Estimated ilmenite content of all ilmenite-bearing concentrates.
[9] Estimated rutile content of all rutile-bearing concentrates.

FIJI ISLANDS

Manganese ore	203	[1] 641
Silver (troy ounces)	37,736	24,869

[1] Exports.

Digitized by Google

FRENCH OCEANIA

Exports of phosphate rock from French Oceania (Makatea Island, Tuamotu Archipelago) totaled 245,804 metric tons in 1950 and 277,858 in 1951.

NAURU AND OCEAN ISLANDS

Exports of phosphate rock from Nauru Island were 1,070,358 metric tons in 1950 and 942,945 in 1951. Exports of phosphate rock from Ocean Island were 251,218 metric tons in 1950 and 256,451 in 1951.

NEW CALEDONIA

TABLE 102.—Mineral production, 1950–51, in metric tons

Mineral	1950	1951	Mineral	1950	1951
Chromite	84,801	88,386	Iron ore (thousand tons)	15	----------

PALAU ISLANDS

Exports of phosphate rock from Angaur Island were estimated to be 119,000 metric tons in 1950 and 144,843 in 1951.

PAPUA

The production of gold in Papua totaled 788 troy ounces in 1950 and 248 in 1951. The production of manganese ore totaled 60 metric tons in the year ended June 30, 1950, and 21 in the year ended June 30, 1951. The production of placer platinum was less than 0.5 troy ounce in the year ended June 30, 1950, and 2 ounces in the year ended June 30, 1951.
